Generalized linear model, specified as a full `GeneralizedLinearModel` object constructed using `fitglm` or `stepwiseglm`, or a compacted `CompactGeneralizedLinearModel` object constructed using `compact`.

Xnew1,Xnew2,...,Xnewn

Predictor components. `Xnewi` can be one of:

- Scalar
- Vector
- Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one `Xnew` array, `Xnew` can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.

Output Arguments

ypred

Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

For binomial models, `feval` uses 1 as the `BinomialSize` parameter, so `ypred` is predicted probabilities.

For models with an offset, `feval` uses 0 as the offset value.

Examples

Predict Responses Using feval

Generate a generalized linear model, and plot its responses to a range of input data.

Generate artificial data for the model, Poisson random numbers with two underlying predictors `X(1)` and `X(2)`.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Generate a range of values for `X(1)` and `X(2)`, and plot the model predictions at those values.

```
[Xtest1 Xtest2] = meshgrid(-1:.5:3,-2:.5:2);
Z = feval(mdl,Xtest1,Xtest2);
surf(Xtest1,Xtest2,Z)
```

- “feval” on page 12-35

Tips

- `feval` allows you to easily evaluate predictions of a model when the model was fitted using a table or dataset array. `predict` requires a table or dataset array with the same predictor names, but you can use simple arrays of scalars with `feval`.

Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument.

`random` predicts with added noise.

feval

Class: CompactLinearModel

Evaluate linear regression model prediction

Syntax

```
ypred = feval(md1,Xnew1,Xnew2,...,Xnewn)
```

Description

`ypred = feval(md1,Xnew1,Xnew2,...,Xnewn)` returns the predicted response of `md1` to the new input predictors [`Xnew1`,`Xnew2`,...,`Xnewn`].

Input Arguments

md1 — Linear model object

LinearModel object | CompactLinearModel object

Linear model object, specified as a full LinearModel object constructed using `fitlm` or `stepwiselm`, or a compacted CompactLinearModel object constructed using `compact`.

Xnew1,Xnew2,...,Xnewn — New predictor values

scalar value | numeric vector

New predictor values, specified as a scalar value, numeric vector, or numeric array. You can specify multiple components for this argument. Each vector component must have the same number of elements in each dimension (in other words, each vector must be same size).

If you pass just one `Xnew` array, then `Xnew` can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.

Output Arguments

ypred — Predicted mean values

scalar value | numeric vector

Predicted mean values at $X_{new1}, X_{new2}, \dots, X_{newn}$, returned as a scalar value or numeric vector. `ypred` is the same size as each component of $X_{new1}, X_{new2}, \dots, X_{newn}$.

For models with an offset, `feval` uses 0 as the offset value.

Examples

Plot Different Categorical Levels for Linear Model

Fit a mileage model to the `carsmall` data, including the `Year` categorical predictor. Superimpose fitted curves on a scatter plot of the data.

Load the data and fit a model.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create a scatter plot of the mileage versus weight.

```
gscatter(tbl.Weight,tbl.MPG,tbl.Year);
```

Use `feval` to plot curves of the model predictions for the various years and weights.

```
w = linspace(min(tbl.Weight),max(tbl.Weight))';  
line(w,feval mdl,w,'70','Color','r')  
line(w,feval mdl,w,'76','Color','g')  
line(w,feval mdl,w,'82','Color','b')
```

- “feval” on page 11-38
- “Linear Regression Workflow” on page 11-42

Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument. `predict` also gives confidence intervals on its predictions.

`random` predicts with added noise.

feval

Class: NonLinearModel

Evaluate nonlinear regression model prediction

Syntax

```
ypred = feval(md1,Xnew1,Xnew2,...,Xnewn)
```

Description

`ypred = feval(md1,Xnew1,Xnew2,...,Xnewn)` returns the predicted response of `md1` to the input `[Xnew1,Xnew2,...,Xnewn]`.

Input Arguments

md1

Nonlinear regression model, constructed by `fitnlm`.

Xnew1,Xnew2,...,Xnewn

Predictor components. `Xnewi` can be one of:

- Scalar
- Vector
- Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one `Xnew` array, `Xnew` can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.

Output Arguments

ypred

Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

Examples

Predict a Nonlinear Model from a Table

Create a nonlinear model for auto mileage based on the `carbig` data. Predict the mileage of an average automobile.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(tbl,modelfun,beta0);
```

Find the predicted mileage of an average auto. The data contain some observations with NaN, so compute the mean using `nanmean`.

```
Xnew = nanmean([Horsepower Weight]);
MPGnew = feval(mdl,Xnew)
```

```
MPGnew =
```

```
21.8073
```

- “Predict or Simulate Responses Using a Nonlinear Model” on page 13-10

Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument. `predict` also gives confidence intervals on its predictions.

random predicts with added noise.

ff2n

Two-level full factorial design

Syntax

```
dFF2 = ff2n(n)
```

Description

`dFF2 = ff2n(n)` gives factor settings `dFF2` for a two-level full factorial design with `n` factors. `dFF2` is m -by- n , where m is the number of treatments in the full-factorial design. Each row of `dFF2` corresponds to a single treatment. Each column contains the settings for a single factor, with values of 0 and 1 for the two levels.

Examples

```
dFF2 = ff2n(3)
```

```
dFF2 =
```

```
 0  0  0
 0  0  1
 0  1  0
 0  1  1
 1  0  0
 1  0  1
 1  1  0
 1  1  1
```

fillprox

Class: TreeBagger

Proximity matrix for training data

Syntax

```
B = fillprox(B)
```

```
B = fillprox(B, 'param1', val1, 'param2', val2, ...)
```

Description

`B = fillprox(B)` computes a proximity matrix for the training data and stores it in the Properties field of B.

`B = fillprox(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

'Trees'	Either 'all' or a vector of indices of the trees in the ensemble to be used in computing the proximity matrix. Default is 'all'.
'NumPrint'	Number of training cycles (grown trees) after which <code>TreeBagger</code> displays a diagnostic message showing training progress. Default is no diagnostic messages.

See Also

`CompactTreeBagger.outlierMeasure` | `CompactTreeBagger.proximity`

findobj

Class: grandstream

Find objects matching specified conditions

Syntax

```
hm = findobj(h, 'conditions')
```

Description

The `findobj` method of the `handle` class follows the same syntax as the MATLAB `findobj` command, except that the first argument must be an array of handles to objects.

`hm = findobj(h, 'conditions')` searches the handle object array `h` and returns an array of handle objects matching the specified conditions. Only the public members of the objects of `h` are considered when evaluating the conditions.

See Also

`findobj` | `grandstream`

findprop

Class: grandstream

Find property of MATLAB handle object

Syntax

```
p = findprop(h, 'propname')
```

Description

`p = findprop(h, 'propname')` finds and returns the `meta.property` object associated with property name `propname` of scalar handle object `h`. `propname` must be a character vector. It can be the name of a property defined by the class of `h` or a dynamic property added to scalar object `h`.

If no property named `propname` exists for object `h`, an empty `meta.property` array is returned.

See Also

`dynamicprops` | `findobj` | `meta.property` | `grandstream`

finv

F inverse cumulative distribution function

Syntax

$X = \text{finv}(P, V1, V2)$

Description

$X = \text{finv}(P, V1, V2)$ computes the inverse of the *F* cdf with numerator degrees of freedom *V1* and denominator degrees of freedom *V2* for the corresponding probabilities in *P*. *P*, *V1*, and *V2* can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

V1 and *V2* parameters must contain real positive values, and the values in *P* must lie on the interval [0 1].

The *F* inverse function is defined in terms of the *F* cdf as

$$x = F^{-1}(p | v_1, v_2) = \{x : F(x | v_1, v_2) = p\}$$

where

$$p = F(x | v_1, v_2) = \int_0^x \frac{\Gamma\left[\frac{(v_1 + v_2)}{2}\right]}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} \frac{t^{\frac{v_1}{2}-2}}{\left[1 + \left(\frac{v_1}{v_2}\right)t\right]^{\frac{v_1 + v_2}{2}}} dt$$

Examples

Find a value that should exceed 95% of the samples from an *F* distribution with 5 degrees of freedom in the numerator and 10 degrees of freedom in the denominator.

```
x = finv(0.95,5,10)
x =
    3.3258
```

You would observe values greater than 3.3258 only 5% of the time by chance.

fishertest

Fisher's exact test

Syntax

```
h = fishertest(x)
[h,p,stats] = fishertest(x)
[ ___ ] = fishertest(x,Name,Value)
```

Description

`h = fishertest(x)` returns a test decision for Fisher's exact test of the null hypothesis that there are no nonrandom associations between the two categorical variables in `x`, against the alternative that there is a nonrandom association. The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, or `0` otherwise.

`[h,p,stats] = fishertest(x)` also returns the significance level `p` of the test and a structure `stats` containing additional test results, including the odds ratio and its asymptotic confidence interval.

`[___] = fishertest(x,Name,Value)` returns a test decision using additional options specified by one or more name-value pair arguments. For example, you can change the significance level of the test or conduct a one-sided test.

Examples

Conduct Fisher's Exact Test

In a small survey, a researcher asked 17 individuals if they received a flu shot this year, and whether they caught the flu this winter. The results indicate that, of the nine people who did not receive a flu shot, three got the flu and six did not. Of the eight people who received a flu shot, one got the flu and seven did not.

Create a 2-by-2 contingency table containing the survey data. Row 1 contains data for the individuals who did not receive a flu shot, and row 2 contains data for the individuals who received a flu shot. Column 1 contains the number of individuals who got the flu, and column 2 contains the number of individuals who did not.

```
x = table([3;1],[6;7], 'VariableNames', {'Flu', 'NoFlu'}, 'RowNames', {'NoShot', 'Shot'})
```

```
x =
```

```
2×2 table
```

	Flu	NoFlu
NoShot	3	6
Shot	1	7

Use Fisher's exact test to determine if there is a nonrandom association between receiving a flu shot and getting the flu.

```
h = fishertest(x)
```

```
h =
```

```
logical
```

```
0
```

The returned test decision $h = 0$ indicates that `fishertest` does not reject the null hypothesis of no nonrandom association between the categorical variables at the default 5% significance level. Therefore, based on the test results, individuals who do not get a flu shot do not have different odds of getting the flu than those who got the flu shot.

Conduct a One-Sided Fisher's Exact Test

In a small survey, a researcher asked 17 individuals if they received a flu shot this year, and whether they caught the flu. The results indicate that, of the nine people who did not receive a flu shot, three got the flu and six did not. Of the eight people who received a flu shot, one got the flu and seven did not.

```
x = [3,6;1,7];
```

Use a right-tailed Fisher's exact test to determine if the odds of getting the flu is higher for individuals who did not receive a flu shot than for individuals who did. Conduct the test at the 1% significance level.

```
[h,p,stats] = fishertest(x, 'Tail', 'right', 'Alpha', 0.01)

h =
    logical
     0

p =
    0.3353

stats =
    struct with fields:
        OddsRatio: 3.5000
        ConfidenceInterval: [0.1289 95.0408]
```

The returned test decision $h = 0$ indicates that `fishertest` does not reject the null hypothesis of no nonrandom association between the categorical variables at the 1% significance level. Since this is a right-tailed hypothesis test, the conclusion is that individuals who do not get a flu shot do not have greater odds of getting the flu than those who got the flu shot.

Generate a Contingency Table Using `crosstab`

Load the hospital data.

```
load hospital
```

The `hospital` dataset array contains data on 100 hospital patients, including last name, gender, age, weight, smoking status, and systolic and diastolic blood pressure measurements.

To determine if smoking status is independent of gender, use `crosstab` to create a 2-by-2 contingency table of smokers and nonsmokers, grouped by gender.

```
[tbl,chi2,p,labels] = crosstab(hospital.Sex,hospital.Smoker)
```

```
tbl =  
  40  13  
  26  21  
  
chi2 =  
  4.5083  
  
p =  
  0.0337  
  
labels =  
  2×2 cell array  
  'Female'  '0'  
  'Male'    '1'
```

The rows of the resulting contingency table `tbl` correspond to the patient's gender, with row 1 containing data for females and row 2 containing data for males. The columns correspond to the patient's smoking status, with column 1 containing data for nonsmokers and column 2 containing data for smokers. The returned result `chi2 = 4.5083` is the value of the chi-squared test statistic for a chi-squared test of independence. The returned value `p = 0.0337` is an approximate *P*-value based on the chi-squared distribution.

Use the contingency table generated by `crosstab` to perform Fisher's exact test on the data.

```
[h,p,stats] = fishertest(tbl)  
  
h =  
  logical  
  1
```

```
p =  
    0.0375  
  
stats =  
    struct with fields:  
        OddsRatio: 2.4852  
        ConfidenceInterval: [1.0624 5.8135]
```

The result `h = 1` indicates that `fishertest` rejects the null hypothesis of nonassociation between smoking status and gender at the 5% significance level. In other words, there is an association between gender and smoking status. The odds ratio indicates that the male patients have about 2.5 times greater odds of being smokers than the female patients.

The returned *P*-value of the test, `p = 0.0375`, is close to, but not exactly the same as, the result obtained by `crosstab`. This is because `fishertest` computes an exact *P*-value using the sample data, while `crosstab` uses a chi-squared approximation to compute the *P*-value.

Input Arguments

x — Contingency table

2-by-2 matrix of nonnegative integer values | 2-by-2 table of nonnegative integer values

Contingency table, specified as a 2-by-2 matrix or table containing nonnegative integer values. A contingency table contains the frequency distribution of the variables in the sample data. You can use `crosstab` to generate a contingency table from sample data.

Example: `[4,0;0,4]`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alpha', 0.01, 'Tail', 'right'` specifies a right-tailed hypothesis test at the 1% significance level.

'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

'Tail' — Type of alternative hypothesis

'both' (default) | 'right' | 'left'

Type of alternative hypothesis, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both'

Two-tailed test. The alternative hypothesis is that there is a nonrandom association between the two variables in X , and the odds ratio is not equal to 1.

'right'

Right-tailed test. The alternative hypothesis is that the odds ratio is greater than 1.

'left'

Left-tailed test. The alternative hypothesis is that the odds ratio is less than 1.

Example: `'Tail', 'right'`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If `h` is 1, then `fishertest` rejects the null hypothesis at the `Alpha` significance level.
- If `h` is 0, then `fishertest` fails to reject the null hypothesis at the `Alpha` significance level.

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. `p` is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of `p` cast doubt on the validity of the null hypothesis.

stats — Test data

structure

Test data, returned as a structure with the following fields:

- `OddsRatio` — A measure of association between the two variables.
- `ConfidenceInterval` — Asymptotic confidence interval for the odds ratio. If any of the cell frequencies in `x` are 0, then `fishertest` does not compute a confidence interval and instead displays [-Inf Inf].

Definitions

Fisher's Exact Test

Fisher's exact test is a nonparametric statistical test used to test the null hypothesis that no nonrandom associations exist between two categorical variables, against the alternative that there is a nonrandom association between the variables.

Fisher's exact test provides an alternative to the chi-squared test for small samples, or samples with very uneven marginal distributions. Unlike the chi-squared test, Fisher's exact test does not depend on large-sample distribution assumptions, and instead calculates an exact *p*-value based on the sample data. Although Fisher's exact test is valid for samples of any size, it is not recommended for large samples because it is computationally intensive. If all of the frequency counts in the contingency table are greater than or equal to `1e7`, then `fishertest` errors. For contingency tables that contain large count values or are well-balanced, use `crosstab` or `chi2gof` instead.

`fishertest` accepts a 2-by-2 contingency table as input, and computes the p -value of the test as follows:

- 1 Calculate the sums for each row, column, and total number of observations in the contingency table.
- 2 Using a multivariate generalization of the hypergeometric probability function, calculate the conditional probability of observing the exact result in the contingency table if the null hypothesis were true, given its row and column sums. The conditional probability is

$$P_{cutoff} = \frac{(R_1!R_2!)(C_1!C_2!)}{N! \prod_{i,j} n_{ij}!},$$

where R_1 and R_2 are the row sums, C_1 and C_2 are the column sums, N is the total number of observations in the contingency table, and n_{ij} is the value in the i th row and j th column of the table.

- 3 Find all possible matrices of nonnegative integers consistent with the row and column sums. For each matrix, calculate the associated conditional probability using the equation for P_{cutoff} .
- 4 Use these values to calculate the p -value of the test, based on the alternative hypothesis of interest.
 - For a two-sided test, sum all of the conditional probabilities less than or equal to P_{cutoff} for the observed contingency table. This represents the probability of observing a result as extreme as, or more extreme than, the actual outcome if the null hypothesis were true. Small p -values cast doubt on the validity of the null hypothesis, in favor of the alternative hypothesis of association between the variables.
 - For a left-sided test, sum the conditional probabilities of all the matrices with a (1,1) cell frequency less than or equal to n_{11} .
 - For a right-sided test, sum the conditional probabilities of all the matrices with a (1,1) cell frequency greater than or equal to n_{11} in the observed contingency table.

The odds ratio is

$$OR = \frac{n_{11}n_{22}}{n_{21}n_{12}}.$$

The null hypothesis of conditional independence is equivalent to the hypothesis that the odds ratio equals 1. The left-sided alternative is equivalent to an odds ratio less than 1, and the right-sided alternative is equivalent to an odds ratio greater than 1.

The asymptotic $100(1 - \alpha)\%$ confidence interval for the odds ratio is

$$CI = \left[\exp\left(L - \Phi^{-1}\left(\frac{1-\alpha}{2}\right)SE\right), \exp\left(L + \Phi^{-1}\left(\frac{1-\alpha}{2}\right)SE\right) \right],$$

where L is the log odds ratio, $\Phi^{-1}(\cdot)$ is the inverse of the normal inverse cumulative distribution function, and SE is the standard error for the log odds ratio. If the $100(1 - \alpha)\%$ confidence interval does not contain the value 1, then the association is significant at the α significance level. If any of the four cell frequencies are 0, then `fishertest` does not compute the confidence interval and instead displays `[-Inf Inf]`.

`fishertest` only accepts 2-by-2 contingency tables as input. To test the independence of categorical variables with more than two levels, use the chi-squared test provided by `crosstab`.

`chi2gof` | `crosstab`

Introduced in R2014b

ClassificationDiscriminant.fit

Class: ClassificationDiscriminant

Fit discriminant analysis classifier (to be removed)

Compatibility

ClassificationDiscriminant.fit will be removed in a future release. Use fitcdiscr instead.

Syntax

```
obj = ClassificationDiscriminant.fit(x,y)
obj = ClassificationDiscriminant.fit(x,y,Name,Value)
```

Description

obj = ClassificationDiscriminant.fit(x,y) returns a discriminant analysis classifier based on the input variables (also known as predictors, features, or attributes) x and output (response) y.

obj = ClassificationDiscriminant.fit(x,y,Name,Value) fits a classifier with additional options specified by one or more Name,Value pair arguments. If you use one of the following five options, obj is of class ClassificationPartitionedModel: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. Otherwise, obj is of class ClassificationDiscriminant.

Input Arguments

x — Predictor values

matrix of numeric values

Predictor values, specified as a matrix of numeric values. Each column of x represents one variable, and each row represents one observation.

`ClassificationDiscriminant.fit` considers NaN values in `x` as missing values. `ClassificationDiscriminant.fit` does not use observations with missing values for `x` in the fit.

Example:

Data Types: `single` | `double`

y — Classification values

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Classification values, specified as a numeric vector, categorical vector (nominal or ordinal), logical vector, character array, or cell array of character vectors. Each row of `y` represents the classification of the corresponding row of `x`.

`ClassificationDiscriminant.fit` considers NaN values in `y` to be missing values. `ClassificationDiscriminant.fit` does not use observations with missing values for `y` in the fit.

Data Types: `single` | `double` | `logical` | `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

'ClassNames' — Class names

array

Class names, specified as the comma-separated pair consisting of `'ClassNames'` and an array. Use the data type that exists in `y`. The default is the class names that exist in `y`. Use `ClassNames` to order the classes or to select a subset of classes for training.

Data Types: `single` | `double` | `logical` | `char`

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of `'Cost'` and a square matrix, where `Cost(i, j)` is the cost of classifying a point into class

j if its true class is i . Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Data Types: `single` | `double` | `struct`

'CrossVal' — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross validate later by passing `Mdl` to `crossval`.

Example: 'CrossVal', 'on'

'CVPartition' — Cross-validated model partition

`cvpartition` object

Cross-validated model partition, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

'Delta' — Linear coefficient threshold

0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of 'Delta' and a nonnegative scalar value. If a coefficient of `Mdl` has magnitude smaller than `Delta`, `Mdl` sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be 0 for quadratic discriminant models.

Data Types: single | double

'DiscrimType' — Discriminant type

'linear' (default) | 'quadratic' | 'diagLinear' | 'diagQuadratic' |
'pseudoLinear' | 'pseudoQuadratic'

Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and a character vector in this table.

Value	Description	Predictor Covariance Treatment
'linear'	Regularized linear discriminant analysis (LDA)	<ul style="list-style-type: none"> All classes have the same covariance matrix. $\hat{\Sigma}_\gamma = (1 - \gamma)\hat{\Sigma} + \gamma\text{diag}(\hat{\Sigma})$. <p>$\hat{\Sigma}$ is the empirical, pooled covariance matrix and γ is the amount of regularization.</p>
'diaglinear'	LDA	All classes have the same, diagonal covariance matrix.
'pseudolinear'	LDA	All classes have the same covariance matrix. The software inverts the covariance matrix using the pseudo inverse.
'quadratic'	Quadratic discriminant analysis (QDA)	The covariance matrices can vary among classes.
'diagquadratic'	QDA	The covariance matrices are diagonal and can vary among classes.
'pseudoquadratic'	QDA	The covariance matrices can vary among classes. The software inverts the covariance matrix using the pseudo inverse.

Note: To use regularization, you must specify 'linear'. To specify the amount of regularization, use the **Gamma** name-value pair argument.

Example: 'DiscrimType', 'quadratic'

'FillCoeffs' — Coeffs property flag

'on' | 'off'

Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and 'on' or 'off'. Setting the flag to 'on' populates the **Coeffs** property in the classifier object. This can be computationally intensive, especially when cross validating. The default is 'on', unless you specify a cross validation name-value pair, in which case the flag is set to 'off' by default.

Example: 'FillCoeffs', 'off'

'Gamma' — Amount of regularization

scalar value in the interval [0,1]

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the interval [0,1]. **Gamma** provides finer control over the covariance matrix structure than **DiscrimType**.

- If you specify 0, then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.
 - For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the covariance matrix. You can display the chosen regularization amount by entering `Mdl.Gamma` at the command line.
 - For quadratic discriminant analysis, if at least one class has an empirical covariance matrix that is singular, then the software throws an error.
- If you specify a value in the interval (0,1), then you must implement linear discriminant analysis, otherwise the software throws an error. Consequently, the software sets **DiscrimType** to 'linear'.
- If you specify 1, then the software uses maximum regularization for covariance matrix estimation. That is, the software restricts the covariance matrix to

be diagonal. Alternatively, you can set `DiscrimType` to `'diagLinear'` or `'diagQuadratic'` for diagonal covariance matrices.

Example: `'Gamma', 1`

Data Types: `single` | `double`

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', ρ` , then the software:

- 1 Randomly reserves $\rho * 100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify, e.g., `'KFold', k` , then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold', 8`

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout'`, `'on'`, then, for each of the n observations, where n is `size(Mdl.X,1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in the cells of a n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Example: `'Leaveout'`, `'on'`

Data Types: `char`

'PredictorNames' — Predictor variable names

`{'X1','X2',...}` (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in `X`.

Data Types: `cell`

'Prior' — Prior probabilities

`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- `'empirical'` determines class probabilities from class frequencies in `y`. If you pass observation weights, they are used to compute the class probabilities.
- `'uniform'` sets all class probabilities equal.
- A vector containing one scalar value for each class.
- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as `y`

- **S.ClassProbs** containing a vector of corresponding probabilities

Example: 'Prior', 'uniform'

Data Types: single | double | char | struct

'ResponseName' — Response variable name

'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector containing the name of the response variable y.

Example: 'ResponseName', 'Response'

Data Types: char

'SaveMemory' — Flag to save covariance matrix

'off' (default) | 'on'

Flag to save covariance matrix, specified as the comma-separated pair consisting of 'SaveMemory' and either 'on' or 'off'. If you specify 'on', then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The predict method computes the full covariance matrix for prediction, and does not store the matrix. If you specify 'off', then `fitcdiscr` computes and stores the full covariance matrix in `Mdl`.

Specify `SaveMemory` as 'on' when the input matrix contains thousands of predictors.

Example: 'SaveMemory', 'on'

'ScoreTransform' — Score transform function

'none' (default) | character vector | function handle

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a function handle or value in this table.

Value	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$

Value	Formula
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: function_handle | char

'Weights' — Observation weights

ones(size(X,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of Weights is the number of rows in X. fitcdiscr normalizes the weights to sum to 1.

Data Types: single | double

Output Arguments

obj — Discriminant analysis classifier

classifier object

Discriminant analysis classifier, returned as a classifier object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class ClassificationPartitionedModel. You

cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `obj` is of class `ClassificationDiscriminant`, and you can use the `predict` method to predict the response of new data.

Examples

Construct a Discriminant Analysis Classifier

Load the sample data.

```
load fisheriris
```

Construct a discriminant analysis classifier using the sample data.

```
obj = ClassificationDiscriminant.fit(meas,species)
```

```
obj =
```

```
ClassificationDiscriminant
  ResponseName: 'Y'
  CategoricalPredictors: []
    ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
  NumObservations: 150
  DiscrimType: 'linear'
    Mu: [3×4 double]
    Coeffs: [3×3 struct]
```

Definitions

Discriminant Classification

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model assumes X has a Gaussian mixture distribution (`gmdistribution`).
- For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
- For quadratic discriminant analysis, both means and covariances of each class vary.

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \operatorname{argmin}_{y=1,\dots,K} \sum_{k=1}^K \hat{P}(k|x) C(y|k),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(k|x)$ is the posterior probability of class k for observation x .
- $C(y|k)$ is the cost of classifying an observation as y when its true class is k .

For details, see “How the `predict` Method Classifies” on page 17-6.

Alternatives

The `classify` function also performs discriminant analysis. `classify` is usually more awkward to use:

- `classify` requires you to fit the classifier every time you make a new prediction.
- `classify` does not perform cross validation.
- `classify` requires you to fit the classifier when changing prior probabilities.

ClassificationKNN.fit

Class: ClassificationKNN

Fit k -nearest neighbor classifier (to be removed)

Compatibility

`ClassificationKNN.fit` will be removed in a future release. Use `fitcknn` instead.

Syntax

```
mdl = ClassificationKNN.fit(X,y)
mdl = ClassificationKNN.fit(X,y,Name,Value)
```

Description

`mdl = ClassificationKNN.fit(X,y)` returns a classification model based on the input variables (also known as predictors, features, or attributes) X and output (response) y .

`mdl = ClassificationKNN.fit(X,y,Name,Value)` fits a model with additional options specified by one or more `Name,Value` pair arguments.

If you use one of these options, `mdl` is of class `ClassificationPartitionedModel`: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Otherwise, `mdl` is of class `ClassificationKNN`.

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each column of X represents one variable, and each row represents one observation.

The length of `Y` and the number of observations in `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

Y — Classification values

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Classification values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors, with the same number of rows as `X`. Each row of `Y` represents the classification of the corresponding row of `X`.

Data Types: `single` | `double` | `cell` | `logical` | `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BreakTies' — Tie-breaking algorithm

`'smallest'` (default) | `'nearest'` | `'random'`

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the `K` nearest neighbors.

Example: `'BreakTies', 'nearest'`

'BucketSize' — Maximum data points in node

50 (default) | positive integer value

Maximum number of data points in the leaf node of the *kd*-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer value. This argument is meaningful only when NSMethod is 'kdtree'.

Example: 'BucketSize',40

Data Types: single | double

'CategoricalPredictors' — Categorical predictor flag

[] (default) | 'all'

Categorical predictor flag, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- 'all' — All predictors are categorical.
- [] — No predictors are categorical.

When you set CategoricalPredictors to 'all', the default Distance is 'hamming'.

Example: 'CategoricalPredictors','all'

'ClassNames' — Class names

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in *y*.

Use ClassNames to order the classes or to select a subset of classes for training. The default is the class names in *y*.

Data Types: single | double | char | logical | cell

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where Cost(*i*, *j*) is the cost of classifying a point into class *j* if its true class is *i* (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of Cost, additionally specify the ClassNames name-value pair argument.

- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `Y`, and `S.ClassificationCosts` containing the cost matrix.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Data Types: `single` | `double` | `struct`

'Cov' — Covariance matrix

`nancov(X)` (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when `'Distance'` is `'mahalanobis'`.

You cannot simultaneously specify `'Standardize'` and either of `'Scale'` or `'Cov'`.

Data Types: `single` | `double`

'CrossVal' — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`. If `'on'`, `fitcknn` creates a cross-validated model with 10 folds. Use the `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` parameters to override this cross-validation setting. You can only use one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross validate `mdl` later using the `crossval` method.

Example: `'Crossval', 'on'`

'CVPartition' — Cross-validated model partition

`cvpartition` object

Cross-validated model partition, specified as the comma-separated pair consisting of `'CVPartition'` and an object created using `cvpartition`. You can only use one of these four options at a time to create a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

'Distance' — Distance metric

character vector | function handle

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see NSMethod).

NSMethod	Distance Metric Names
exhaustive	Any distance metric of ExhaustiveSearcher
kdtree	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

This table includes valid distance metrics of ExhaustiveSearcher.

Distance Metric Names	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix C . The default value of C is the sample covariance matrix of X , as computed by <code>nancov(X)</code> . To specify a different value for C , use the 'Cov' name-value pair argument.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'Exponent' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S . The default value of S is the standard deviation computed from X , <code>S = nanstd(X)</code> . To specify another value for S , use the 'Scale' name-value pair argument.

Distance Metric Names	Description
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	Distance function handle. <i>distfun</i> has the form <pre>function D2 = DISTFUN(ZI,ZJ) % calculation of distance ... where</pre> <ul style="list-style-type: none"> • ZI is a 1-by-N vector containing one row of X or Y. • ZJ is an M2-by-N matrix containing multiple rows of X or Y. • D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(J,:).

If you specify `CategoricalPredictors` as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

For definitions, see “Distance Metrics” on page 18-10.

Example: 'Distance', 'minkowski'

Data Types: `function_handle` | `char`

'DistanceWeight' — Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | `function handle`

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the values in this table.

Value	Description
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance ²
@ <i>fcn</i>	<i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).

Example: 'DistanceWeight', 'inverse'

Data Types: function_handle | char

'Exponent' — Minkowski distance exponent

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent', 3

Data Types: single | double

'Holdout' — Fraction of data for holdout validation

0 (default) | scalar value in the range [0, 1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0, 1]. Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

If you use Holdout, you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout', 0.1

Data Types: single | double

'IncludeTies' — Tie inclusion flag

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether predict includes all the neighbors whose distance values are equal to the Kth smallest distance. If IncludeTies is true, predict includes all these neighbors. Otherwise, predict uses exactly K neighbors.

Example: 'IncludeTies', true

Data Types: logical

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold',8

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Specify 'on' to use leave-one-out cross validation.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout', 'on'

'NSMethod' — Nearest neighbor search method

'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- 'kdtree' — Create and use a *kd*-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
 - 'euclidean'
 - 'cityblock'
 - 'minkowski'
 - 'chebychev'
- 'exhaustive' — Use the exhaustive search algorithm. The distance values from all points in X to each point in Y are computed to find nearest neighbors.

The default is 'kdtree' when X has 10 or fewer columns, X is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

Example: 'NSMethod', 'exhaustive'

'NumNeighbors' — Number of nearest neighbors to find

1 (default) | positive integer value

Number of nearest neighbors in X to find for classifying each point when predicting, specified as the comma-separated pair consisting of `'NumNeighbors'` and a positive integer value.

Example: `'NumNeighbors',3`

Data Types: `single` | `double`

'PredictorNames' — Predictor variable names

`{'x1','x2',...}` (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in X .

If you specify the predictors as a table (`tbl`), then `PredictorNames` must be a subset of the variable names in `tbl`. In this case, the software uses only the variables in `PredictorNames` to train the model. If you use `formula` to specify the model, then you cannot use the `PredictorNames` name-value pair.

Example: `'PredictorNames',{'PedalWidth','PedalLength'}`

Data Types: `cell`

'Prior' — Prior probabilities

`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
<code>'empirical'</code>	The class prior probabilities are the class relative frequencies in Y .
<code>'uniform'</code>	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.

Value	Description
structure	<p>A structure <code>S</code> with two fields:</p> <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior', 'uniform'`

Data Types: `single` | `double` | `struct`

'ResponseName' — Response variable name

`'Y'` (default) | character vector

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector containing the name of the response variable `Y`.

This name-value pair is not valid when using the `ResponseVarName` or `formula` input arguments.

Example: `'ResponseName', 'Response'`

Data Types: `char`

'Scale' — Distance scale

`nanstd(X)` (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of `'Scale'` and a vector containing nonnegative scalar values with length equal to the number of columns in `X`. Each coordinate difference between `X` and a query point is scaled by the corresponding element of `Scale`. This argument is only valid when `'Distance'` is `'seuclidean'`.

You cannot simultaneously specify `'Standardize'` and either of `'Scale'` or `'Cov'`.

Data Types: `single` | `double`

'Weights' — Observation weights`ones(size(X,1),1) (default) | vector of scalar values`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values. The software weighs the observations in each row of `X` or `tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `tbl`.

If you specify the input data as a table `tbl`, then `Weights` can be the name of a variable in `tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector containing the variable name. For example, if the weights vector `w` is stored as `tbl.w`, then specify it as `'w'`. Otherwise, the software treats all columns of `tbl`, including `w`, as predictors when training the model.

The software normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: `single` | `double`

Output Arguments

mdl — Classifier model

classifier model object

k -nearest neighbor classifier model, returned as a classifier model object.

Note that using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

Examples

Train a k -Nearest Neighbor Classifier

Construct a k -nearest neighbor classifier for Fisher's iris data, where k , the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

```
load fisheriris
X = meas;
Y = species;
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a 5-nearest neighbors classifier. It is good practice to standardize noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1)
```

```
Mdl =
```

```
ClassificationKNN
    ResponseName: 'Y'
  CategoricalPredictors: []
        ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    NumObservations: 150
           Distance: 'euclidean'
    NumNeighbors: 5
```

Mdl is a trained `ClassificationKNN` classifier, and some of its properties display in the Command Window.

To access the properties of Mdl, use dot notation.

```
Mdl.ClassNames
Mdl.Prior
```

```
ans =
```

```
3×1 cell array
    'setosa'
    'versicolor'
    'virginica'
```

```
ans =  
  
    0.3333    0.3333    0.3333
```

`Mdl.Prior` contains the class prior probabilities, which are settable using the name-value pair argument `'Prior'` in `fitcknn`. The order of the class prior probabilities corresponds to the order of the classes in `Mdl.ClassNames`. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3 respectively.

```
Mdl.Prior = [0.5 0.2 0.3];
```

You can pass `Mdl` to, for example, `predict (ClassificationKNN)` to label new measurements, or `crossval (ClassificationKNN)` to cross validate the classifier.

Train a *k*-Nearest Neighbor Classifier Using the Minkowski Metric

Load Fisher's iris data set.

```
load fisheriris  
X = meas;  
Y = species;
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of character vectors that contains the corresponding iris species.

Train a 3-nearest neighbors classifier using the Minkowski metric. To use the Minkowski metric, you must use an exhaustive searcher. It is good practice to standardize noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',3,...  
    'NSMethod','exhaustive','Distance','minkowski',...  
    'Standardize',1);
```

`Mdl` is a `ClassificationKNN` classifier.

You can examine the properties of `Mdl` by double-clicking `Mdl` in the Workspace window. This opens the Variable Editor.

Name	Value	Min	Max
Mdl	1x1 ClassificationKNN		
meas	150x4 double	0.1000	7.9
species	150x1 cell		
X	150x4 double	0.1000	7.9
Y	150x1 cell

Definitions

Prediction

`ClassificationKNN` predicts the classification of a point X_{new} using a procedure equivalent to this:

- 1 Find the `NumNeighbors` points in the training set X that are nearest to X_{new} .
- 2 Find the `NumNeighbors` response values Y to those nearest points.
- 3 Assign the classification label Y_{new} that has the largest posterior probability among the values in Y .

For details, see “Posterior Probability” on page 29-4877 in the `predict` documentation.

ClassificationTree.fit

Class: ClassificationTree

Fit classification tree (to be removed)

Compatibility

ClassificationTree.fit will be removed in a future release. Use fitctree instead.

Syntax

```
tree = ClassificationTree.fit(x,y)
tree = ClassificationTree.fit(x,y,Name,Value)
```

Description

`tree = ClassificationTree.fit(x,y)` returns a classification tree based on the input variables (also known as predictors, features, or attributes) x and output (response) y . `tree` is a binary tree, where each branching node is split based on the values of a column of x .

`tree = ClassificationTree.fit(x,y,Name,Value)` fits a tree with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note that using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `ClassificationTree`, and you can use the `predict` method to make predictions.

Input Arguments

x — Predictor values

matrix of floating point values

Predictor values, specified as a matrix of floating point values.

`ClassificationTree.fit` considers NaN values in `x` as missing values.

`ClassificationTree.fit` does not use observations with all missing values for `x` in the fit. `ClassificationTree.fit` uses observations with some missing values for `x` to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

y — predictor values

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Predictor values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors.

Each row of `y` represents the classification of the corresponding row of `x`. For numeric `y`, consider using `fitrtree` instead. `ClassificationTree.fit` considers NaN values in `y` to be missing values.

`ClassificationTree.fit` does not use observations with missing values for `y` in the fit.

Data Types: `single` | `double` | `char` | `logical` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

'AlgorithmForCategorical' — Algorithm for best split on categorical predictor
'Exact' | 'PullLeft' | 'PCA' | 'OVAbyClass'

Algorithm to find the best split on a categorical predictor with L levels for data with $K \geq 3$ classes, specified as the comma-separated pair consisting of `'AlgorithmForCategorical'` and one of the following.

'Exact'	Consider all $2^{L-1} - 1$ combinations
'PullLeft'	Pull left by purity
'PCA'	Principal component-based partition
'OVByClass'	One versus all by class

`ClassificationTree.fit` selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For $K = 2$ classes, `ClassificationTree.fit` always performs the exact search.

Example: `'AlgorithmForCategorical', 'PCA'`

'CategoricalPredictors' — Categorical predictors list

numeric or logical vector | cell array of character vectors | character matrix | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following.

- A numeric vector with indices from 1 to p , where p is the number of columns of x .
- A logical vector of length p , where a `true` entry means that the corresponding column of x is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

Example: `'CategoricalPredictors', 'all'`

Data Types: `single` | `double` | `char`

'ClassNames' — Class names

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in y .

Use `ClassNames` to order the classes or to select a subset of classes for training. The default is the class names that exist in y .

Data Types: `single` | `double` | `char` | `logical` | `cell`

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification a point, specified as the comma-separated pair consisting of 'Cost' and one of the following.

- Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if `i~j`, and `Cost(i, j)=0` if `i=j`

Data Types: `single` | `double` | `struct`

'CrossVal' — Flag to grow cross-validated tree

'off' (default) | 'on'

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', `ClassificationTree.fit` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. Note that you can only use one of these four options ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate `tree` later using the `crossval` method.

Example: `'CrossVal', 'on'`

'CVPartition' — Partition for cross-validation tree

`cvpartition` object

Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object of the `cvpartition` class created using `cvpartition`.

Note that if you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

'Holdout' — Fraction of data for holdout validation

1 (default) | scalar value in the range (0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

Note that if you use 'Holdout', you cannot use any of the 'CVPartition', 'Kfold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout',0.1

Data Types: single | double

'Kfold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'Kfold' and a positive integer value.

Note that if you use 'Kfold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'Kfold',8

Data Types: single | double

'Leaveout' — Leave-one-out cross validation flag

'off' (default) | 'on'

Leave-one-out cross validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'Kfold' name-value pair arguments.

Example: 'Leaveout','on'

'MaxCat' — Maximum category levels

10 (default) | nonnegative scalar value

Maximum category levels, specified as the comma-separated pair consisting of 'MaxCat' and a nonnegative scalar value. `ClassificationTree.fit` splits a categorical

predictor using the exact search algorithm if the predictor has at most `MaxCat` levels in the split node. Otherwise, `ClassificationTree.fit` finds the best categorical split using one of the inexact algorithms.

Note that passing a small value can lead to loss of accuracy and passing a large value can lead to long computation time and memory overload.

Example: `'MaxCat', 8`

'MergeLeaves' — Leaf merge flag

`'on'` (default) | `'off'`

Leaf merge flag, specified as the comma-separated pair consisting of `'MergeLeaves'` and either `'on'` or `'off'`. When `'on'`, `ClassificationTree.fit` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When `'off'`, `ClassificationTree.fit` does not merge leaves.

Example: `'MergeLeaves', 'off'`

'MinLeaf' — Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of `'MinLeaf'` and a positive integer value. Each leaf has at least `MinLeaf` observations per tree leaf. If you supply both `MinParent` and `MinLeaf`, `ClassificationTree.fit` uses the setting that gives larger leaves: `MinParent=max(MinParent,2*MinLeaf)`.

Example: `'MinLeaf', 3`

Data Types: `single` | `double`

'MinParent' — Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of `'MinParent'` and a positive integer value. Each branch node in the tree has at least `MinParent` observations. If you supply both `MinParent` and `MinLeaf`, `ClassificationTree.fit` uses the setting that gives larger leaves: `MinParent=max(MinParent,2*MinLeaf)`.

Example: `'MinParent', 8`

Data Types: `single` | `double`

'NVarToSample' — Number of predictors for split

`'all'` | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NVarToSample'` and a positive integer value. You can also specify `'all'` to use all available predictors.

Example: `'NVarToSample',3`

Data Types: `single` | `double`

'PredictorNames' — Predictor variable names

`{'x1','x2',...}` (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in `x`.

'Prior' — Prior probabilities

`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- `'empirical'` determines class probabilities from class frequencies in `y`. If you pass observation weights, they are used to compute the class probabilities.
- `'uniform'` sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as `y`
 - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `weights` and `prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior','uniform'`

'Prune' — Pruning flag

`'on'` (default) | `'off'`

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', `ClassificationTree.fit` grows the classification tree, and computes the optimal sequence of pruned subtrees. When 'off' `ClassificationTree.fit` grows the classification tree without pruning.

Example: 'Prune', 'off'

'PruneCriterion' — Pruning criterion

'error' (default) | 'impurity'

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and either 'error' or 'impurity'.

Example: 'PruneCriterion', 'impurity'

'ResponseName' — Response variable name

'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector representing the name of the response variable y .

Example: 'ResponseName', 'Response'

'ScoreTransform' — Score transform function

'none' | 'symmetric' | 'invlogit' | 'ismax' | function handle | ...

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Alternatively, you can specify one of the following values representing a built-in transformation function.

Value	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$

Value	Formula
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

Example: 'ScoreTransform', 'logit'

'SplitCriterion' — Split criterion

'gdi' (default) | 'twoing' | 'deviance'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

Example: 'SplitCriterion', 'deviance'

'Surrogate' — Surrogate decision splits flag

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When set to 'on', `ClassificationTree.fit` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `ClassificationTree.fit` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `ClassificationTree.fit` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: 'Surrogate', 'on'

'Weights' — Observation weights

`ones(size(x,1),1)` (default) | vector of scalar values

Vector of observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values. The length of `Weights` is equal to the number of rows in `x`. `ClassificationTree.fit` normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: `single` | `double`

Output Arguments

tree — Classification tree

classification tree object

Classification tree object, returned as a classification tree object.

Note that using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method. Instead, use `kfoldpredict` to predict responses for observations not used for training.

Otherwise, `tree` is of class `ClassificationTree`, and you can use the `predict` method to make predictions.

Examples

Construct a Classification Tree

Construct a classification tree for the data in `ionosphere.mat`.

```
load ionosphere
tc = ClassificationTree.fit(X,Y)
```

```
tc =
```

```
ClassificationTree
```

```

      ResponseName: 'Y'
CategoricalPredictors: []
      ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
NumObservations: 351

```

Definitions

Impurity and Node Error

ClassificationTree splits nodes based on either *impurity* or *node error*.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a *pure* node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance (`'deviance'`) — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule (`'twoing'`) — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R)\left(\sum_i |L(i) - R(i)|\right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is $1 - p(j)$.

Topics

GeneralizedLinearModel.fit

Class: GeneralizedLinearModel

Create generalized linear regression model

Compatibility

GeneralizedLinearModel.fit will be removed in a future release. Use fitglm instead.

Syntax

```
mdl = GeneralizedLinearModel.fit(tbl)
mdl = GeneralizedLinearModel.fit(X,y)
mdl = GeneralizedLinearModel.fit(...,modelspec)
mdl = GeneralizedLinearModel.fit(...,Name,Value)
mdl = GeneralizedLinearModel.fit(...,modelspec,Name,Value)
```

Description

`mdl = GeneralizedLinearModel.fit(tbl)` creates a generalized linear model of a table or dataset array `tbl`.

`mdl = GeneralizedLinearModel.fit(X,y)` creates a generalized linear model of the responses `y` to a data matrix `X`.

`mdl = GeneralizedLinearModel.fit(...,modelspec)` creates a generalized linear model as specified by `modelspec`.

`mdl = GeneralizedLinearModel.fit(...,Name,Value)` or `mdl = GeneralizedLinearModel.fit(...,modelspec,Name,Value)` creates a generalized linear model with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-58).

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

modelspec — Model specification

character vector specifying the model | t -by- $(p+1)$ terms matrix | character vector of the form 'Y ~ terms'

Model specification, which is the starting model for `stepwiseglm`, specified as one of the following:

- Character vector specifying the type of model.

Character Vector	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- t -by- $(p+1)$ matrix, namely terms matrix, specifying terms to include in model, where t is the number of terms and p is the number of predictor variables, and plus one is for the response variable.
- Character vector representing a formula in the form `'Y ~ terms'`, where the `terms` are in “Wilkinson Notation” on page 29-1752.

Example: `'quadratic'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinomialSize' — Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter `n` for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double`

'CategoricalVars' — Categorical variables

cell array of character vectors | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of character vectors of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

'DispersionFlag' — Indicator to compute dispersion parameter

false for `'binomial'` and `'poisson'` distributions (default) | true

Indicator to compute dispersion parameter for `'binomial'` and `'poisson'` distributions, specified as the comma-separated pair consisting of `'DispersionFlag'` and one of the following.

<code>true</code>	Estimate a dispersion parameter when computing standard errors
<code>false</code>	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

Example: `'DispersionFlag', true`

'Distribution' — Distribution of the response variable

`'normal'` (default) | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of the response variable, specified as the comma-separated pair consisting of `'Distribution'` and one of the following.

<code>'normal'</code>	Normal distribution
<code>'binomial'</code>	Binomial distribution
<code>'poisson'</code>	Poisson distribution
<code>'gamma'</code>	Gamma distribution
<code>'inverse gaussian'</code>	Inverse Gaussian distribution

Example: `'Distribution', 'gamma'`

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude', [2,3]`

Example: `'Exclude', logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

'Intercept' — Indicator for constant term

`true` (default) | `false`

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either `true` to include or `false` to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector, not a formula or matrix.

Example: 'Intercept', false

'Link' — Link function

The canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
'comploglog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: <ul style="list-style-type: none"> • S.Link — The link function • S.Inverse — The inverse link function • S.Derivative — The derivative of the link function 	$f(\mu) = \mathbf{S}.\text{Link}(\mu)$	$\mu = \mathbf{S}.\text{Inverse}(Xb)$

The link function defines the relationship $f(\mu) = X^*b$ between the mean response μ and the linear combination of predictors X^*b .

For more information on the canonical link functions, see [Definitions](#).

Example: 'Link', 'probit'

'Offset' – Offset variable

[] (default) | vector | character vector

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

`fitglm` and `stepwiseglm` use `Offset` as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is $\mu \sim \text{Offset} + (\text{terms involving real predictors})$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: single | double | char

'PredictorVars' – Predictor variables

cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The character vectors should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars', [2,3]

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `cell`

'ResponseVar' — Response variable

last column in `tbl` (default) | character vector containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char`

'VarNames' — Names of variables in fit

`{'x1','x2',...,'xn','y'}` (default) | cell array of character vectors

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of character vectors including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `cell`

'Weights' — Observation weights

`ones(n,1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: single | double

Output Arguments

mdl — Generalized linear model

GeneralizedLinearModel object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a GeneralizedLinearModel object.

For properties and methods of the generalized linear model object, mdl, see the GeneralizedLinearModel class page.

Examples

Fit a Generalized Linear Model

Fit a logistic regression model of probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.

```
load hospital
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```
mdl = fitglm(ds,modelspec,'Distribution','binomial')
```

```
mdl =
```

Generalized linear regression model:

```
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
Distribution = Binomial
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

100 observations, 93 error degrees of freedom

Dispersion: 1

Chi²-statistic vs. constant model: 5.07, p-value = 0.535

The large *P*-value indicates the model might not differ statistically from a constant.

- “Generalized Linear Model Workflow” on page 12-40

Definitions

Terms Matrix

A terms matrix is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and plus one is for the response variable.

The value of $T(i, j)$ is the exponent of variable j in term i . Suppose there are three predictor variables A, B, and C:

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
dsa = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{ 'Sex', 'BloodPressure', 'Age', 'Smoker' });
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0     0     0     0
1     0     0     0
0     0     1     0
0     0     0     1
```

Redefine the dataset array.

```
dsa = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker,'VarNames',{ 'BloodPressure', 'Sex', 'Age', 'Smoker' });
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0     0     0     0
0     1     0     0
0     0     1     0
0     0     0     1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```
    0    0    0
    1    0    0
    0    1    0
    1    1    0
    0    2    0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

```
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = stepwiselm(X,MPG,[0 0 0], 'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:

$y \sim 1 + x2$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

Formula

A formula for model specification is a character vector of the form ' $Y \sim terms$ '

where

- Y is the response name.
- $terms$ contains
 - Variable names
 - $+$ means include the next variable
 - $-$ means do not include the next variable
 - $:$ defines an interaction, a product of terms
 - $*$ defines an interaction **and all lower-order terms**

- \wedge raises the predictor to a power, exactly as in $*$ repeated, so \wedge includes lower order terms as well
- $()$ groups terms

Note: Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a B^2 term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because B^2 includes a B term.

' $Y \sim A + B + C + A:B$ ' includes an $A*B$ term.

' $Y \sim A*B + C$ ' is the same as the previous example because $A*B = A + B + A:B$.

' $Y \sim A*B*C - A:B:C$ ' has all interactions among A , B , and C , except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of A with each of the other variables.

Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$

Wilkinson Notation	Factors in Standard Notation
A*B*C - A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
- For other methods such as `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

Alternatives

You can also construct a generalized linear model using `fitglm`.

Use `stepwiseglm` to select a model specification automatically. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

gmdistribution.fit

Class: gmdistribution

Gaussian mixture parameter estimates

Note: `fit` will be removed in a future release. Use `fitgmdist` instead.

Syntax

```
obj = gmdistribution.fit(X,k)
obj = gmdistribution.fit(...,param1,val1,param2,val2,...)
```

Description

`obj = gmdistribution.fit(X,k)` uses an Expectation Maximization (EM) algorithm to construct an object `obj` of the `gmdistribution` class containing maximum likelihood estimates of the parameters in a Gaussian mixture model with `k` components for data in the n -by- d matrix `X`, where n is the number of observations and d is the dimension of the data.

`gmdistribution` treats NaN values as missing data. Rows of `X` with NaN values are excluded from the fit.

`obj = gmdistribution.fit(...,param1,val1,param2,val2,...)` provides control over the iterative EM algorithm. Parameters and values are listed below.

Parameter	Value
'Start'	Method used to choose initial component parameters. One of the following: <ul style="list-style-type: none"> 'randSample' — To select <code>k</code> observations from <code>X</code> at random as initial component means. The mixing proportions are uniform.

Parameter	Value
	<p>The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of $X(:, j)$. This is the default.</p> <ul style="list-style-type: none"> • 'plus' — The software selects k observations from X using the <code>kmeans++</code> algorithm. The initial mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of $X(:, j)$. • <code>S</code> — A structure array with fields <code>mu</code>, <code>Sigma</code>, and <code>PComponents</code>. See <code>gmdistribution</code> for descriptions of values. • <code>s</code> — A vector of length n containing an initial guess of the component index for each point.
'Replicates'	A positive integer giving the number of times to repeat the EM algorithm, each time with a new set of parameters. The solution with the largest likelihood is returned. A value larger than 1 requires the 'randSample' start method. The default is 1.
'CovType'	'diagonal' if the covariance matrices are restricted to be diagonal; 'full' otherwise. The default is 'full'.
'SharedCov'	Logical <code>true</code> if all the covariance matrices are restricted to be the same (pooled estimate); logical <code>false</code> otherwise.
'Regularize'	A nonnegative regularization number added to the diagonal of covariance matrices to make them positive-definite. The default is 0.
'Options'	Options structure for the iterative EM algorithm, as created by <code>statset.gmdistribution.fit</code> uses the parameters 'Display' with a default value of 'off', 'MaxIter' with a default value of 100, and 'TolFun' with a default value of $1e-6$.

In some cases, `gmdistribution` may converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

The following issues may result in an ill-conditioned covariance matrix:

- The number of dimension of your data is relatively high and there are not enough observations.
- Some of the features (variables) of your data are highly correlated.
- Some or all the features are discrete.

- You tried to fit the data to too many components.

In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:

- Pre-process your data to remove correlated features.
- Set 'SharedCov' to true to use an equal covariance matrix for every component.
- Set 'CovType' to 'diagonal'.
- Use 'Regularize' to add a very small positive number to the diagonal of every covariance matrix.
- Try another set of initial values.

In other cases `gmdistribution` may pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Trying another set of initial values may avoid this issue without altering your data or model.

Examples

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function:

```
MU1 = [1 2];  
SIGMA1 = [2 0; 0 .5];  
MU2 = [-3 -5];  
SIGMA2 = [1 0; 0 1];  
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];  
  
scatter(X(:,1),X(:,2),10,'.')  
hold on
```

Next, fit a two-component Gaussian mixture model:

```
options = statset('Display','final');  
obj = gmdistribution.fit(X,2,'Options',options);  
10 iterations, log-likelihood = -7046.78  
  
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

Among the properties of the fit are the parameter estimates:

```
ComponentMeans = obj.mu
ComponentMeans =
    0.9391    2.0322
   -2.9823   -4.9737

ComponentCovariances = obj.Sigma
ComponentCovariances(:,:,1) =
    1.7786   -0.0528
   -0.0528    0.5312
ComponentCovariances(:,:,2) =
    1.0491   -0.0150
   -0.0150    0.9816
```

```
MixtureProportions = obj.PComponents
MixtureProportions =
    0.5000    0.5000
```

The Akaike information is minimized by the two-component model:

```
AIC = zeros(1,4);
obj = cell(1,4);
for k = 1:4
    obj{k} = gmdistribution.fit(X,k);
    AIC(k) = obj{k}.AIC;
end

[minAIC,numComponents] = min(AIC);
numComponents
numComponents =
    2
```

```
model = obj{2}
model =
Gaussian mixture distribution
with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean:      0.9391    2.0322
Component 2:
Mixing proportion: 0.500000
Mean:     -2.9823   -4.9737
```

Both the Akaike and Bayes information are negative log-likelihoods for the data with penalty terms for the number of estimated parameters. They are often used to determine an appropriate number of components for a model when the number of components is unspecified.

LinearModel.fit

Class: LinearModel

Create linear regression model

Compatibility

LinearModel.fit will be removed in a future release. Use fitlm instead.

Syntax

```
mdl = LinearModel.fit(tbl)
mdl = LinearModel.fit(X,y)
mdl = LinearModel.fit( ____,modelspec)
mdl = LinearModel.fit( ____,Name,Value)
mdl = LinearModel.fit( ____,modelspec,Name,Value)
```

Description

mdl = LinearModel.fit(tbl) creates a linear model of a table or dataset array tbl.

mdl = LinearModel.fit(X,y) creates a linear model of the responses y to a data matrix X.

mdl = LinearModel.fit(____,modelspec) creates a linear model of the type specified by modelspec, using any of the previous syntaxes.

mdl = LinearModel.fit(____,Name,Value) or mdl = LinearModel.fit(____,modelspec,Name,Value) creates a linear model with additional options specified by one or more Name,Value pair arguments. For example, you can specify which predictor variables to include in the fit or include observation weights.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-58). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double`

modelspec — Model specification

character vector naming the model | t -by- $(p + 1)$ terms matrix | character vector of the form 'Y ~ terms'

Model specification, specified as one of the following.

- A character vector naming the model.

Character Vector	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- t -by- $(p + 1)$ matrix, namely terms matrix, specifying terms to include in the model, where t is the number of terms and p is the number of predictor variables, and plus 1 is for the response variable.
- A character vector representing a formula in the form 'Y ~ terms', where the terms are specified using Wilkinson Notation.

Example: 'quadratic'

Example: 'y ~ X1 + X2^2 + X1:X2'

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'CategoricalVars' — Categorical variables

cell array of character vectors | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of character vectors of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

```
Example: 'CategoricalVars',[2,3]
```

```
Example: 'CategoricalVars',logical([0 1 1 0 0 0])
```

Data Types: `single` | `double` | `logical`

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

```
Example: 'Exclude',[2,3]
```

```
Example: 'Exclude',logical([0 1 1 0 0 0])
```

Data Types: `single` | `double` | `logical`

'Intercept' — Indicator for constant term

`true` (default) | `false`

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of `'Intercept'` and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a character vector, not a formula or matrix.

Example: `'Intercept', false`

'PredictorVars' — Predictor variables

cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of `'PredictorVars'` and either a cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The character vectors should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars', [2,3]`

Example: `'PredictorVars', logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `cell`

'ResponseVar' — Response variable

last column in `tbl` (default) | character vector containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar', 'yield'`

Example: `'ResponseVar', [4]`

Example: `'ResponseVar', logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char`

'RobustOpts' — Indicator of robust fitting type

'off' (default) | 'on' | character vector | structure with character vector or function handle

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of 'RobustOpts' and one of the following.

- 'off' — No robust fitting. `fitlm` uses ordinary least squares.
- 'on' — Robust fitting. When you use robust fitting, 'bisquare' weight function is the default.
- Character vector — Name of the robust fitting weight function from the following table. `fitlm` uses the corresponding default tuning constant in the table.
- Structure with the character vector `RobustWgtFun` containing the name of the robust fitting weight function from the following table and optional scalar `Tune` fields — `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. You can choose the name of the robust fitting weight function from this table. If you do not supply a `Tune` field, the fitting function uses the corresponding default tuning constant.

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339
'bisquare' (default)	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(-(r.^2))$	2.985

The value r in the weight functions is

$$r = \text{resid} / (\text{tune} * s * \sqrt{1-h}),$$

where `resid` is the vector of residuals from the previous iteration, `h` is the vector of leverage values from a least-squares fit, and `s` is an estimate of the standard deviation of the error term given by

$$s = \text{MAD}/0.6745.$$

MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are p columns in X , the smallest p absolute deviations are excluded when computing the median.

Default tuning constants give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

- Structure with the function handle `RobustWgtFun` and optional scalar `Tune` fields — You can specify a custom weight function. `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. Specify `RobustWgtFun` as a function handle that accepts a vector of residuals, and returns a vector of weights the same size. The fitting function scales the residuals, dividing by the tuning constant (default 1) and by an estimate of the error standard deviation before it calls the weight function.

Example: `'RobustOpts', 'andrews'`

'VarNames' — Names of variables in fit

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | cell array of character vectors

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: `cell`

'Weights' — Observation weights

`ones(n,1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: `single` | `double`

Output Arguments

`mdl` — Linear model

`LinearModel` object

Linear model representing a least-squares fit of the response to the data, returned as a `LinearModel` object.

If the value of the 'RobustOpts' name-value pair is not `[]` or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

For properties and methods of the linear model object, see the `LinearModel` class page.

Examples

Linear Regression Model of Matrix Data

Fit a linear model of the Hald data.

Load the data.

```
load hald
X = ingredients; % Predictor variables
y = heat; % Response
```

Fit a default linear model to the data.

```
mdl = fitlm(X,y)
```

```
mdl =
```

Linear regression model:
 $y \sim 1 + x1 + x2 + x3 + x4$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	62.405	70.071	0.8906	0.39913
x1	1.5511	0.74477	2.0827	0.070822
x2	0.51017	0.72379	0.70486	0.5009
x3	0.10191	0.75471	0.13503	0.89592
x4	-0.14406	0.70905	-0.20317	0.84407

Number of observations: 13, Error degrees of freedom: 8
 Root Mean Squared Error: 2.45
 R-squared: 0.982, Adjusted R-Squared 0.974
 F-statistic vs. constant model: 111, p-value = 4.76e-07

Linear Regression with Categorical Predictor

Fit a model of a table that contains a categorical predictor.

Load the `carsmall` data.

```
load carsmall
```

Construct a table containing continuous predictor variable `Weight`, nominal predictor variable `Year`, and response variable `MPG`.

```
tbl = table(MPG,Weight);  
tbl.Year = nominal(Model_Year);
```

Create a fitted model of `MPG` as a function of `Year`, `Weight`, and `Weight^2`. (You don't have to include `Weight` explicitly in your formula because it is a lower-order term of `Weight^2`) and is included automatically.

```
mdl = fitlm(tbl,'MPG ~ Year + Weight^2')
```

```
mdl =
```

Linear regression model:

```
MPG ~ 1 + Weight + Year + Weight^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 2.78

R-squared: 0.885, Adjusted R-Squared 0.88

F-statistic vs. constant model: 172, p-value = 5.52e-41

`fitlm` creates two dummy (indicator) variables for the nominal variate, `Year`. The dummy variable `Year_76` takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year. The corresponding model is

$$\hat{MPG} = 54.206 - 0.0164(\text{Weight}) + 2.0887(\text{Year}_76) + 8.1864(\text{Year}_82) + 1.557e - 06(\text{Weight}^2)$$

Specify Response and Predictor Variables for Linear Model

Fit a linear regression model to sample data. Specify the response and predictor variables, and include only pairwise interaction terms in the model.

Load sample data.

```
load hospital
```

Fit a linear model with interaction terms to the data. Specify `weight` as the response variable, and `sex`, `age`, and `smoking status` as the predictor variables. Also, specify that `sex` and `smoking status` are categorical variables.

```
mdl = fitlm(hospital, 'interactions', 'ResponseVar', 'Weight', ...
    'PredictorVars', {'Sex', 'Age', 'Smoker'}, ...
    'CategoricalVar', {'Sex', 'Smoker'})
```

```
mdl =
```

```
Linear regression model:
```

```
Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	118.7	7.0718	16.785	6.821e-30
Sex_Male	68.336	9.7153	7.0339	3.3386e-10
Age	0.31068	0.18531	1.6765	0.096991
Smoker_1	3.0425	10.446	0.29127	0.77149
Sex_Male:Age	-0.49094	0.24764	-1.9825	0.050377
Sex_Male:Smoker_1	0.9509	3.8031	0.25003	0.80312
Age:Smoker_1	-0.07288	0.26275	-0.27737	0.78211

```
Number of observations: 100, Error degrees of freedom: 93
```

```
Root Mean Squared Error: 8.75
```

```
R-squared: 0.898, Adjusted R-Squared 0.892
```

```
F-statistic vs. constant model: 137, p-value = 6.91e-44
```

The weight of the patients do not seem to differ significantly according to age, or the status of smoking, or interaction of these factors with patient sex at the 5% significance level.

Fit a Robust Linear Regression Model

Fit a linear regression model using a robust fitting method.

Load the sample data.

```
load hald
```

The `hald` data measures the effect of cement composition on its hardening heat. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The array `heat` contains the heat of hardening after 180 days for each cement sample.

Fit a robust linear model to the data.

```
mdl = fitlm(ingredients,heat,'linear','RobustOpts','on')
```

```
mdl =
```

```
Linear regression model (robust fit):
  y ~ 1 + x1 + x2 + x3 + x4
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

```
Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979, Adjusted R-Squared 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
```

Definitions

Terms Matrix

A terms matrix is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and plus one is for the response variable.

The value of $T(i, j)$ is the exponent of variable j in term i . Suppose there are three predictor variables A, B, and C:

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
```

```
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
dsa = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0     0     0     0
1     0     0     0
0     0     1     0
0     0     0     1
```

Redefine the dataset array.

```
dsa = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0     0     0     0
0     1     0     0
```

```

0    0    1    0
0    0    0    1

```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```

load carsmall
X = [Acceleration,Weight];

```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```

0    0    0
1    0    0
0    1    0
1    1    0
0    2    0

```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

```

Linear regression model:
y ~ 1 + x1*x2 + x2^2

```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1
 R-squared: 0.751, Adjusted R-Squared 0.739
 F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and `x2` term, which correspond to the `Weight` variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = stepwiselm(X,MPG,[0 0 0], 'upper',T)
```

1. Adding `x2`, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:

`y ~ 1 + x2`

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
<code>x2</code>	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

Formula

A formula for model specification is a character vector of the form '`Y ~ terms`'

where

- `Y` is the response name.
- `terms` contains
 - Variable names

- + means include the next variable
- - means do not include the next variable
- : defines an interaction, a product of terms
- * defines an interaction **and all lower-order terms**
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower order terms as well
- () groups terms

Note: Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include - 1 in the formula.

For example,

'Y ~ A + B + C' means a three-variable linear model with intercept.

'Y ~ A + B + C - 1' is a three-variable linear model without intercept.

'Y ~ A + B + C + B^2' is a three-variable model with intercept and a B^2 term.

'Y ~ A + B^2 + C' is the same as the previous example because B^2 includes a B term.

'Y ~ A + B + C + A:B' includes an A*B term.

'Y ~ A*B + C' is the same as the previous example because $A*B = A + B + A:B$.

'Y ~ A*B*C - A:B:C' has all interactions among A, B, and C, except the three-way interaction.

'Y ~ A*(B + C + D)' has all linear terms, plus products of A with each of the other variables.

Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	A, B, $A*B$

Wilkinson Notation	Factors in Standard Notation
A:B	A*B only
-B	Do not include B
A*B + C	A, B, C, A*B
A + B + C + A:B	A, B, C, A*B
A*B*C - A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

Tips

- Use robust fitting (`RobustOpts` name-value pair) to reduce the effect of outliers automatically.
- Do not use robust fitting when you want to subsequently adjust a model using `step`.
- For other methods or properties of the `LinearModel` object, see `LinearModel`.

Algorithms

The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is `robustfit`.

Alternatives

You can also construct a linear model using `fitlm`.

You can construct a model in a range of possible models using `stepwiselm`. However, you cannot use robust regression and stepwise regression together.

LinearMixedModel.fit

Class: LinearMixedModel

Fit linear mixed-effects model using tables

Compatibility

LinearMixedModel.fit will be removed in a future release. Use fitlme instead.

Syntax

```
lme = LinearMixedModel.fit(tbl,formula)
```

```
lme = LinearMixedModel.fit(tbl,formula,Name,Value)
```

Description

`lme = LinearMixedModel.fit(tbl,formula)` returns a linear mixed-effects model, specified by `formula`, fitted to the variables in the table or dataset array `tbl`.

`lme = LinearMixedModel.fit(tbl,formula,Name,Value)` returns a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-58). You must specify the model for the variables using `formula`.

Data Types: `single` | `double` | `char` | `cell`

formula — Formula for model specification

character vector of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a character vector of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For full description, see “Formula” on page 29-1800.

Example: `'y ~ treatment +(1|block)'`

Data Types: `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'CovariancePattern' — Pattern of covariance matrix

`'FullCholesky'` (default) | character vector | square symmetric logical matrix | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of `'CovariancePattern'` and a character vector, a square symmetric logical matrix, or a cell array of character vectors or logical matrices.

If there are R random-effects terms, then the value of `'CovariancePattern'` must be a cell array of length R , where each element r of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

`'FullCholesky'`

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

`'Full'`

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

`'CompSymm'`

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

`PAT`

Square symmetric logical matrix. If `'CovariancePattern'` is defined by the matrix `PAT`, and if `PAT(a,b) = false`, then the `(a,b)` element of the corresponding covariance matrix is constrained to be 0.

Example: `'CovariancePattern', 'Diagonal'`

Example: `'CovariancePattern', {'Full', 'Diagonal'}`

'FitMethod' — Method for estimating parameters

`'ML'` (default) | `'REML'`

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of `'FitMethod'` and either of the following.

`'ML'`

Default. Maximum likelihood estimation

`'REML'`

Restricted maximum likelihood estimation

Example: `'FitMethod', 'REML'`

'Weights' — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n , where n is the number of observations.

Data Types: `single` | `double`**'Exclude' — Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude', [13,67]`Data Types: `single` | `double` | `logical`**'DummyVarCoding' — Coding to use for dummy variables**`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the following.

Value	Description
<code>'reference'</code>	Default. Coefficient for first category set to 0.
<code>'effects'</code>	Coefficients sum to 0.
<code>'full'</code>	One dummy variable for each category.

Example: `'DummyVarCoding', 'effects'`**'Optimizer' — Optimization algorithm**`'quasinevton'` (default) | `'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

<code>'quasinevton'</code>	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
<code>'fminunc'</code>	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> with <code>'Algorithm'</code> set to <code>'quasi-newton'</code> .

Example: `'Optimizer', 'fminunc'`

'OptimizerOptions' — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of `'OptimizerOptions'` and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If `'Optimizer'` is `'fminunc'`, then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options `'fminunc'` uses. If `'Optimizer'` is `'fminunc'` and you do not supply `'OptimizerOptions'`, then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.
- If `'Optimizer'` is `'quasinevton'`, then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The `'quasinevton'` optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

'ToIFun' — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

'ToIX' — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

'MaxIter' — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

'Display' — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

'StartMethod' — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

Value	Description
'default'	An internally defined default value
'random'	A random initial value

Example: 'StartMethod', 'random'

'Verbose' — Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: `'Verbose', true`

'CheckHessian' — Indicator to check positive definiteness of Hessian

`false` (default) | `true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either `false` or `true`. Default is `false`.

Specify 'CheckHessian' as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: `'CheckHessian', true`

Output Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

Examples

Random-Intercept Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the response variable `FluRate`, the nominal variable `Region`

that shows which region each estimate is from, the nationwide estimate WtdILI, and the grouping variable Date.

```
flu2 = stack(flu,2:10, 'NewDataVarName', 'FluRate', ...
            'IndVarName', 'Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with the nationwide a random intercept that varies by Date. The model corresponds to

$$y_{im} = \beta_0 + \beta_1 \text{WtdILI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable Date, b_{0m} is the random effect for level m of the grouping variable Date, and ε_{im} is the observation error for observation i . The random effect has the prior distribution,

$$b_{0m} \sim N(0, \sigma_b^2),$$

and the error term has the distribution,

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
lme = LinearMixedModel.fit(flu2, 'FluRate ~ 1 + WtdILI + (1|Date)')
```

```
lme =
```

```

'(Intercept)'	0.16385	0.057525	2.8484	466	0.0045885
'WtdILI'	0.7236	0.032219	22.459	466	3.0502e-76
Lower	Upper				
0.050813	0.27689				
0.66028	0.78691				

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower
'(Intercept)'	'(Intercept)'	'std'	0.17146	0.13227
Upper				
0.22226				

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits for the standard deviation of the random-effects term, σ_b , do not include 0 (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` (`LinearMixedModel`) method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
```

```

y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')

y_hat =
    1.4674

```

You can display the fitted value using the `fitted` method.

```

F = fitted(lme);
F(28)

ans =
    1.4674

```

Randomized-Block Design

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'));
```

The dataset array shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator, to assess if there is significant difference in the performance according to the time of the shift. Use the restricted maximum likelihood method and `'effects'` contrasts.

`'effects'` contrasts mean that the coefficients sum to 0, and `LinearMixedModel.fit` creates a matrix called a *fixed effects design matrix* to describe the effect of Shift. This matrix has two columns, `Shift_Evening` and `Shift_Morning`, where

$$\text{Shift_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

$$\text{Shift_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

The model corresponds to

$$\begin{aligned} \text{Morning Shift:} \quad \text{QCDev}_{im} &= \beta_0 + \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im}, \\ \text{Evening Shift:} \quad \text{QCDev}_{im} &= \beta_0 + \beta_1 \text{Shift_Evening}_i + b_{0m} + \epsilon_{im}, \\ \text{Night Shift:} \quad \text{QCDev}_{im} &= \beta_0 - \beta_1 \text{Shift_Evening}_i - \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im}, \end{aligned}$$

where i represents the observations, and m represents the operators, $i = 1, 2, \dots, 15$, and $m = 1, 2, \dots, 5$. The random effects and the observation error have the following distributions:

$$b_{0m} \sim N(0, \sigma_b^2)$$

and

$$\epsilon_{im} \sim N(0, \sigma^2).$$

```
lme = LinearMixedModel.fit(shift, 'QCDev ~ Shift + (1|Operator)', ...

```

```
B =
```

```

0.5775
1.1757
-2.1715
2.3655
-1.9472

```

The estimated absolute deviation from the target quality characteristics for the third operator working in the evening shift is

$$\begin{aligned}\hat{y}_{\text{Evening,Operator3}} &= \hat{\beta}_0 + \hat{\beta}_1 \text{Shift_Evening} + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);  
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans =
```

```
0.9481
```

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working in the morning shift is

$$\begin{aligned}\hat{y}_{\text{Morning,Operator3}} &= \hat{\beta}_0 + \hat{\beta}_2 \text{Shift_Morning} + \hat{b}_{03} \\ &= 3.6525 - 0.91973 - 2.1715 \\ &= 0.56127.\end{aligned}$$

You can also display this value in the following way.

```
F(shift.Shift=='Morning' & shift.Operator=='3')
```

```
ans =
```

```
0.5613
```

The operator tends to make a smaller magnitude of error in the morning shift.

Split-Plot Experiment

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'));
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into

five plots, where five types of tomato plants, (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. Then, the tomato plants in the plots are divided into subplots, where each subplot is treated by one of the four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

$$y_{imjk} = \beta_0 + \sum_{m=2}^4 \beta_{1m} I[F]_{im} + \sum_{j=2}^5 \beta_{2j} I[T]_{ij} + \sum_{j=2}^5 \sum_{m=2}^4 \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S * T)_{jk} + \epsilon_{imjk},$$

where $i = 1, 2, \dots, 60$, the index m corresponds to the fertilizer types, j corresponds to the tomato types, and $k = 1, 2, 3$ corresponds to the blocks (soil). S_k represents the k th soil type, and $(S * T)_{jk}$ represents the j th tomato type nested in the k th soil type. $I[F]_{im}$ is the dummy variable representing level m of the fertilizer. Similarly, $I[T]_{ij}$ is the dummy variable representing the level j of the tomato type.

The random effects and observation error have the following prior distributions:

$$b_{0k} \sim N(0, \sigma_S^2)$$

$$b_{0jk} \sim N(0, \sigma_{S*T}^2)$$

$$\epsilon_{imjk} \sim N(0, \sigma^2)$$

```
lme = LinearMixedModel.fit(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)
```

```
lme =
```

The P -values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the `anova` (`LinearMixedModel`) method after refitting the model using `'effects'` contrasts.

The confidence interval for the standard deviations of the random-effects terms (σ^2), where the intercept is grouped by soil is very large. This term does not appear significant.

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term (`1 | Soil`).

You can compare the two models using the `compare` (`LinearMixedModel`) method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term will be tested.

Longitudinal Study with a Covariate

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six two-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`LinearMixedModel.fit` uses Program A as a reference and creates the necessary dummy variables $I[\cdot]$. Since the model already has an intercept, `LinearMixedModel.fit` only creates dummy variables for program types B, C, D. This is also known as the 'reference' method of coding dummy variables.

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\ + \beta_6 (\text{Week}_i * I[\text{PB}]_i) + \beta_7 (\text{Week}_i * I[\text{PC}]_i) + \beta_8 (\text{Week}_i * I[\text{PD}]_i) \\ + b_{0m} + b_{1m} \text{Week}_{im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. `IW` stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[\text{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```

'Res Std' 0.10261 0.087882 0.11981

The *P*-values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in Program B is significantly different relative to the weight loss of subjects who are in Program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

Definitions

Formula

In general, a formula for model specification is a character vector of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, `Xj`, which can be continuous or grouping variables
- Grouping variables, `g1`, `g2`, ..., `gR`,

where the grouping variables in `Xj` and `gr` can be categorical, logical, character arrays, or cell arrays of character vectors.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix `X`, `random1` is a specification of the random-effects design matrix `Z1` corresponding to grouping variable `g1`, and similarly `randomR` is a specification of the random-effects design matrix `ZR` corresponding to grouping variable `gR`. You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$)
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, $X1$ and $X2$. This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	No intercept and fixed effects for $X1$ and $X2$. The implicit intercept term is suppressed by including <code>-1</code> .
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable $g1$.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'.

Formula	Description
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Tips

- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix`.

Alternatives

You can also construct a linear mixed-effects model using `fitlme`. If your data is in matrix format, then use `fitlmematrix`.

fit

Class: NaiveBayes

Create Naive Bayes classifier object by fitting training data

Syntax

```
nb = NaiveBayes.fit(training, class)
nb = NaiveBayes.fit(..., 'param1',val1, 'param2',val2, ...)
```

Note: `fit` will be removed in a future release. Use `fitNaiveBayes` instead.

Description

`nb = NaiveBayes.fit(training, class)` builds a `NaiveBayes` classifier object `nb`. `training` is an N-by-D numeric matrix of training data. Rows of `training` correspond to observations; columns correspond to features. `class` is a classing variable for `training` taking K distinct levels. Each element of `class` defines which class the corresponding row of `training` belongs to. `training` and `class` must have the same number of rows.

`nb = NaiveBayes.fit(..., 'param1',val1, 'param2',val2, ...)` specifies one or more of the following name/value pairs:

- `'Distribution'` – a character vector or a 1-by-D cell array of character vectors, specifying which distributions `fit` uses to model the data. If the value is a , `fit` models all the features using one type of distribution. `fit` can also model different features using different types of distributions. If the value is a cell array, its `j`th element specifies the distribution `fit` uses for the `j`th feature. The available types of distributions are:

<code>'normal'</code> (default)	Normal (Gaussian) distribution.
<code>'kernel'</code>	Kernel smoothing density estimate.

- 'mvmn' Multivariate multinomial distribution for discrete data. `fit` assumes each individual feature follows a multinomial model within a class. The parameters for a feature include the probabilities of all possible values that the corresponding feature can take.
- 'mn' Multinomial distribution for classifying the count-based data such as the bag-of-tokens model. In the bag-of-tokens model, the value of the *j*th feature is the number of occurrences of the *j*th token in this observation, so it must be a nonnegative integer. When 'mn' is used, `fit` considers each observation as multiple trials of a multinomial distribution, and considers each occurrence of a token as one trial. The number of categories (bins) in this multinomial model is the number of distinct tokens, i.e., the number of columns of `training`.

If you specify `mn`, then all features are components of a multinomial distribution. Therefore, you cannot include 'mn' as an element of a cell array of character vectors.

- 'Prior' – The prior probabilities for the classes, specified as one of the following:

'empirical' (default) `fit` estimates the prior probabilities from the relative frequencies of the classes in `training`.

'uniform' The prior probabilities are equal for all classes.

vector A numeric vector of length *K* specifying the prior probabilities in the class order of `class`.

structure A structure `S` containing class levels and their prior probabilities. `S` must have two fields:

- `S.prob`: A numeric vector of prior probabilities.
- `S.class`: A vector of the same type as `class`, containing unique class levels indicating the class for the corresponding element of `prob`. `S.class` must contain all the *K* levels in `class`. It can also contain classes that do not appear in `class`. This can be useful if `training` is a subset of a larger training set. `fit` ignores any classes that appear in `S.class` but not in `class`.

If the prior probabilities don't sum to one, `fit` will normalize them.

- `'KSWidth'` – The bandwidth of the kernel smoothing window. The default is to select a default bandwidth automatically for each combination of feature and class, using a value that is optimal for a Gaussian distribution. You can specify the value as one of the following:

scalar	Width for all features in all classes.
row vector	1-by-D vector where the j th element is the bandwidth for the j th feature in all classes.
column vector	K-by-1 vector where the i th element specifies the bandwidth for all features in the i th class. K represents the number of class levels.
matrix	K-by-D matrix M where $M(i, j)$ specifies the bandwidth for the j th feature in the i th class.
structure	A structure S containing class levels and their bandwidths. S must have two fields: <ul style="list-style-type: none"> • <code>S.width</code> – A numeric array of bandwidths specified as a row vector, or a matrix with D columns. • <code>S.class</code> – A vector of the same type as <code>class</code>, containing unique class levels indicating the class for the corresponding row of width.

- `'KSSupport'` – The regions where the density can be applied. It can be `'unbounded'` (default), `'positive'`, a two-element vector as shown below, or a 1-by-D cell array of these values:
 - `'unbounded'` (default) The density can extend over the whole real line.
 - `'positive'` The density is restricted to positive values.
 - `[L,U]` A two-element vector specifying the finite lower bound L and upper bound U for the support of the density.
- `'KSType'` – The type of kernel smoother to use. It can be `'normal'` (default), `'box'`, `'triangle'`, `'epanechnikov'`, or a 1-by-D cell array of these values.

NonLinearModel.fit

Class: NonLinearModel

Fit nonlinear regression model

Compatibility

NonLinearModel.fit will be removed in a future release. Use fitnlm instead.

Syntax

```
mdl = NonLinearModel.fit(tbl,modelfun,beta0)
mdl = NonLinearModel.fit(X,y,modelfun,beta0)
mdl = NonLinearModel.fit(...,modelfun,beta0,Name,Value)
```

Description

mdl = NonLinearModel.fit(tbl,modelfun,beta0) fits the model specified by modelfun to variables in the table or dataset array tbl, and returns the nonlinear model mdl. NonLinearModel.fit estimates model coefficients using an iterative procedure starting from the initial values in beta0.

mdl = NonLinearModel.fit(X,y,modelfun,beta0) fits a nonlinear regression model using the column vector y as a response variable and the columns of the matrix X as predictor variables.

mdl = NonLinearModel.fit(...,modelfun,beta0,Name,Value) fits a nonlinear regression model with additional options specified by one or more Name,Value pair arguments.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. If you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variable must be numeric.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double`

modelfun — Functional form of the model

function handle | character vector of the form ' $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ '

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
 - b is a coefficient vector with the same number of elements as `beta0`.
 - x is a matrix with the same number of columns as X or the number of predictor variable columns of `tbl`.

`modelfun(b, x)` returns a column vector that contains the same number of rows as `x`. Each row of the vector is the result of evaluating `modelfun` on the corresponding row of `x`. In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. `modelfun` should return real numbers to obtain meaningful coefficients.

- Character vector of the form `'y ~ f(b1, b2, ..., bj, x1, x2, ..., xk)'`, where `f` represents a scalar function of the scalar coefficient variables `b1, ..., bj` and the scalar data variables `x1, ..., xk`.

beta0 — Coefficients

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. `NonLinearModel` starts its search for optimal coefficients from `beta0`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'CoefficientNames' — Names of the model coefficients

`{'b1', 'b2', ..., 'bk'}` (default) | cell array of character vectors

Names of the model coefficients, specified as a cell array of character vectors.

Data Types: `char`

'ErrorModel' — Form of the error variance model

`'constant'` (default) | `'proportional'` | `'combined'`

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f , and one or two parameters a and b

<code>'constant'</code> (default)	$y = f + ae$
-----------------------------------	--------------

'proportional'	$y = f + bfe$
'combined'	$y = f + (a + b f)e$

The only allowed error model when using `Weights` is 'constant'.

Note: `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

Example: 'ErrorModel', 'proportional'

'ErrorParameters' — Initial estimates of the error model parameters

numeric array

Initial estimates of the error model parameters for the chosen `ErrorModel`, specified as a numeric array.

Error Model	Parameters	Default Values
'constant'	a	1
'proportional'	b	1
'combined'	a, b	[1,1]

You can only use the 'constant' error model when using `Weights`.

Note: `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for a and the starting value 2 for b as follows.

Example: 'ErrorParameters', [1,2]

Data Types: char

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

'Options' — Options for controlling the iterative fitting procedure

[] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by `statset`. The relevant fields are the nonempty fields in the structure returned by the call `statset('nlinfit')`.

Option	Meaning	Default
DerivStep	Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.	$\text{eps}^{(1/3)}$
Display	Amount of information displayed by the fitting algorithm. <ul style="list-style-type: none"> 'off' — Displays no information. 'final' — Displays the final output. 'iter' — Displays iterative output to the Command Window. 	'off'
FunValCheck	Character vector indicating to check for invalid values, such as NaN or Inf, from the model function.	'on'
MaxIter	Maximum number of iterations allowed. Positive integer.	200

Option	Meaning	Default
RobustWgtFun	Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 29-2453	[]
Tune	Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.	See “Robust Options” on page 29-2453 for the default, which depends on RobustWgtFun.
TolFun	Termination tolerance for the objective function value. Positive scalar.	1e-8
TolX	Termination tolerance for the parameters. Positive scalar.	1e-8

Data Types: struct

'PredictorVars' — Predictor variables

cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The character vectors should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars', [2,3]

Example: 'PredictorVars', logical([0 1 1 0 0 0])

Data Types: single | double | logical | cell

'ResponseVar' — Response variable

last column in `tbl` (default) | character vector containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar', 'yield'`

Example: `'ResponseVar', [4]`

Example: `'ResponseVar', logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char`

'VarNames' — Names of variables in fit

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | cell array of character vectors

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of character vectors including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: `cell`

'Weights' — Observation weights

`ones(n, 1)` (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have n elements, where n is the number of rows in `tbl` or `y`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `NonLinearModel` estimates the error variance at observation `i` by $\text{MSE} \cdot (1/W(i))$, where `MSE` is the mean squared error.

Data Types: `single` | `double` | `function_handle`

Output Arguments

`mdl` — Nonlinear model

`NonLinearModel` object

Nonlinear model representing a least-squares fit of the response to the data, returned as a `NonLinearModel` object.

If the `Options` structure contains a nonempty `RobustWgtFun` field, the model is not a least-squares fit, but uses the `RobustWgtFun` robust fitting function.

For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

Examples

Nonlinear Model from a Table

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(tbl,modelfun,beta0)
```

```
mdl =
```

```
Nonlinear regression model:
MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5
```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

```
Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745, Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113
```

Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(X,y,modelfun,beta0)
```

```
mdl =
```

```
Nonlinear regression model:
y ~ b1 + b2*x1^b3 + b4*x2^b5
```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue

b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387
 Root Mean Squared Error: 3.96
 R-Squared: 0.745, Adjusted R-Squared 0.743
 F-statistic vs. constant model: 283, p-value = 1.79e-113

Adjust Fitting Options in the Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Strive for more accuracy by lowering the `TolFun` option, and observe the iterations by setting the `Display` option.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
```

Create options to lower `TolFun` and to report iterative display, and create a model using the options.

```
opts = statset('Display','iter','TolFun',1e-10);
mdl = NonLinearModel.fit(X,y,modelfun,beta0,'Options',opts);
```

Iteration	SSE	Norm of Gradient	Norm of Step
0	1.82248e+06		
1	678600	788810	1691.07

Specify Nonlinear Regression Using Model Character Vector

Specify a nonlinear regression model for estimation using a function handle or character vector.

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Use a function handle to specify the Hougen-Watson model for the rate data.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0)
```

```
mdl =
```

```
Nonlinear regression model:  
y ~ hougen(b,X)
```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
	-----	-----	-----	-----
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

```
Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 0.193  
R-Squared: 0.999, Adjusted R-Squared 0.998  
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13
```

Alternatively, you can use a character vector to specify the Hougen-Watson model for the rate data.

```
myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';  
mdl2 = NonLinearModel.fit(X,y,myfun,beta0)
```

```
mdl2 =
```

```
Nonlinear regression model:  
y ~ (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)
```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
	-----	-----	-----	-----
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089

b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 0.193
R-Squared: 0.999, Adjusted R-Squared 0.998
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Estimate Nonlinear Regression Using Robust Fitting Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp[-b_3 x] + \epsilon,$$

where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility  
b = [1;3;2];  
x = exprnd(2,100,1);  
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');  
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use a character vector to specify the model.

```
b0 = [2;2;2];  
modelstr = 'y ~ b1 + b2*exp(-b3*x)';  
mdl = NonLinearModel.fit(x,y,modelstr,b0,'Options',opts)
```

```
mdl =
```

```
Nonlinear regression model (robust fit):  
y ~ b1 + b2*exp(- b3*x)
```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
b1	1.0218	0.07202	14.188	2.1344e-25
b2	3.6619	0.25429	14.401	7.974e-26
b3	2.9732	0.38496	7.7232	1.0346e-11

Number of observations: 100, Error degrees of freedom: 97
 Root Mean Squared Error: 0.501
 R-Squared: 0.807, Adjusted R-Squared 0.803
 F-statistic vs. constant model: 203, p-value = 2.34e-35

Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0,'Weights',weights)
```

```
mdl =
```

```
Nonlinear regression model:
y ~ hougen(b,X)
```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
	_____	_____	_____	_____

b1	0.83085	0.58224	1.427	0.19142
b2	0.04095	0.029663	1.3805	0.20477
b3	0.025063	0.019673	1.274	0.23842
b4	0.080053	0.057812	1.3847	0.20353
b5	1.8261	1.281	1.4256	0.19183

Number of observations: 13, Error degrees of freedom: 8
 Root Mean Squared Error: 0.037
 R-Squared: 0.998, Adjusted R-Squared 0.998
 F-statistic vs. zero model: 1.14e+03, p-value = 3.49e-11

Nonlinear Regression Model Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0,'ErrorModel','combined')
```

```
mdl =
```

```
Nonlinear regression model:
y ~ hougen(b,X)
```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
b1	1.2526	0.86702	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075158	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 1.27

R-Squared: 0.999, Adjusted R-Squared 0.998

F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Algorithms

NonLinearModel.fit uses the same fitting algorithm as `nlinfit`.

Alternatives

You can also construct a nonlinear model using `fitnlm`.

RegressionTree.fit

Class: RegressionTree

Binary decision tree for regression (to be removed)

Compatibility

RegressionTree.fit will be removed in a future release. Use fitrtree instead.

Syntax

```
tree = RegressionTree.fit(x,y)
tree = RegressionTree.fit(x,y,Name,Value)
```

Description

`tree = RegressionTree.fit(x,y)` returns a regression tree based on the input variables (also known as predictors, features, or attributes) `x` and output (response) `y`. `tree` is a binary tree where each branching node is split based on the values of a column of `x`.

`tree = RegressionTree.fit(x,y,Name,Value)` fits a tree with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note that using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a tree of class `RegressionPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

Input Arguments

x — Predictor values

matrix of scalar values

Predictor values, specified as a matrix of scalar values. Each column of **x** represents one variable, and each row represents one observation.

`RegressionTree.fit` considers NaN values in **x** as missing values.

`RegressionTree.fit` does not use observations with all missing values for **x** the fit.

`RegressionTree.fit` uses observations with some missing values for **x** to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

y — Response values

vector of scalar values

Response values, specified as a vector of scalar values with the same number of rows as **x**. Each entry in **y** is the response to the data in the corresponding row of **x**.

`RegressionTree.fit` considers NaN values in **y** to be missing values.

`RegressionTree.fit` does not use observations with missing values for **y** in the fit.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'CategoricalPredictors' — Categorical predictors list

numeric or logical vector | cell array of character vectors | character matrix | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following.

- A numeric vector with indices from 1 to **p**, where **p** is the number of columns of **x**.
- A logical vector of length **p**, where a `true` entry means that the corresponding column of **x** is a categorical variable.

- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in the PredictorNames property.
- A character matrix, where each row of the matrix is a name of a predictor variable. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

Example:

Data Types: single | double | logical | char | struct | cell

'CrossVal' — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', `RegressionTree.fit` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. Note that you can only use one of these four options ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the `crossval` method.

Example: 'CrossVal', 'on'

'CVPartition' — Partition for cross-validation tree

cvpartition object

Partition for cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object of the `cvpartition` class created using `cvpartition`.

Note that if you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

Example:

'Holdout' — Fraction of data for holdout validation

scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

Note that if you use `'Holdout'`, you cannot use any of the `'CVPartition'`, `'Kfold'`, or `'Leaveout'` name-value pair arguments.

Example: `'Holdout', 0.1`

Data Types: `single` | `double`

'Kfold' — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of `'Kfold'` and a positive integer value.

Note that if you use `'Kfold'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'Leaveout'` name-value pair arguments.

Example: `'Kfold', 8`

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and either `'on'` or `'off'`. Use leave-one-out cross validation by setting to `'on'`.

Note that if you use `'Leaveout'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'Kfold'` name-value pair arguments.

Example: `'Leaveout', 'on'`

'MergeLeaves' — Leaf merge flag

`'on'` (default) | `'off'`

Leaf merge flag, specified as the comma-separated pair consisting of `'MergeLeaves'` and either `'on'` or `'off'`. When `'on'`, `RegressionTree.fit` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When `'off'`, `RegressionTree.fit` does not merge leaves.

Example: `'MergeLeaves', 'off'`

'MinLeaf' — Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of `'MinLeaf'` and a positive integer value. Each leaf has at least `MinLeaf` observations per tree leaf. If you supply both `MinParent` and `MinLeaf`, `RegressionTree.fit` uses the setting that gives larger leaves: `MinParent=max(MinParent,2*MinLeaf)`.

Example: `'MinLeaf',3`

Data Types: `single` | `double`

'MinParent' — Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of `'MinParent'` and a positive integer value. Each branch node in the tree has at least `MinParent` observations. If you supply both `MinParent` and `MinLeaf`, `RegressionTree.fit` uses the setting that gives larger leaves: `MinParent=max(MinParent,2*MinLeaf)`.

Example: `'MinParent',8`

Data Types: `single` | `double`

'NVarToSample' — Number of predictors for split

'all' (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NVarToSample'` and a positive integer value. You can also specify `'all'` to use all available predictors.

Example: `'NVarToSample',3`

Data Types: `single` | `double`

'PredictorNames' — Predictor variable names

{`'x1'`, `'x2'`, ...} (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in `x`.

Example:

Data Types: `cell`

'Prune' — Pruning flag`'on' (default) | 'off'`

Pruning flag, specified as the comma-separated pair consisting of `'Prune'` and either `'on'` or `'off'`. When `'on'`, `RegressionTree.fit` computes the full tree and the optimal sequence of pruned subtrees. When `'off'`, `RegressionTree.fit` computes the full tree without pruning.

Example: `'Prune', 'off'`

'PruneCriterion' — Pruning criterion`'mse' (default)`

Pruning criterion, specified as the comma-separated pair consisting of `'PruneCriterion'` and `'mse'`.

Example: `'PruneCriterion', 'mse'`

'QEToler' — Quadratic error tolerance`1e-6 (default) | positive scalar value`

Quadratic error tolerance per node, specified as the comma-separated pair consisting of `'QEToler'` and a positive scalar value. Splitting nodes stops when quadratic error per node drops below `QEToler*QED`, where `QED` is the quadratic error for the entire data computed before the decision tree is grown.

Example: `'QEToler', 1e4`

'ResponseName' — Response variable name`'Y' (default) | character vector`

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector containing the name of the response variable in `y`.

Example: `'ResponseName', 'Response'`

Data Types: `char`

'ResponseTransform' — Response transform function`'none' (default) | function handle`

Response transform function for transforming the raw response values, specified as the comma-separated pair consisting of `'ResponseTransform'` and either a function

handle or 'none'. The function handle should accept a matrix of response values and return a matrix of the same size. The default character vector 'none' means $@(x)x$, or no transformation.

Add or change a `ResponseTransform` function using dot notation:

```
tree.ResponseTransform = @function
```

Example:

Data Types: `function_handle`

'SplitCriterion' — Split criterion

'MSE' (default)

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.

Example: 'SplitCriterion', 'MSE'

'Surrogate' — Surrogate decision splits flag

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When 'on', `RegressionTree.fit` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `RegressionTree.fit` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `RegressionTree.fit` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: 'Surrogate', 'on'

Data Types: `single` | `double`

'Weights' — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of `Weights` is the number of rows in `x`.

Example:

Data Types: `single` | `double`

Output Arguments

tree — Regression tree

regression tree object

Regression tree, returned as a regression tree object. Note that using the 'Crossval', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class `RegressionPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

Examples

Predict Values Using a Regression Tree

Load the sample data.

```
load carsmall
```

Construct a regression tree to predict the mileage of cars based on their weights and numbers of cylinders.

```
tree = RegressionTree.fit([Weight, Cylinders],MPG,...  
    'MinParent',20,...  
    'PredictorNames',{ 'W', 'C'})
```

```
tree =
```

```
    RegressionTree  
    PredictorNames: { 'W'  'C' }
```

```
      ResponseName: 'Y'  
CategoricalPredictors: []  
      ResponseTransform: 'none'  
      NumObservations: 94
```

Predict the mileage of a car that weighs 2200 lbs and has four cylinders.

```
predict(tree,[2200,4])
```

```
ans =
```

```
29.6111
```

fitcdiscr

Fit discriminant analysis classifier

Syntax

```
Mdl = fitcdiscr(Tbl,ResponseVarName)
```

```
Mdl = fitcdiscr(Tbl,formula)
```

```
Mdl = fitcdiscr(Tbl,Y)
```

```
Mdl = fitcdiscr(X,Y)
```

```
Mdl = fitcdiscr( ____,Name,Value)
```

Description

`Mdl = fitcdiscr(Tbl,ResponseVarName)` returns a fitted discriminant analysis model based on the input variables (also known as predictors, features, or attributes) contained in the table `Tbl` and output (response or labels) contained in `ResponseVarName`.

`Mdl = fitcdiscr(Tbl,formula)` returns a fitted discriminant analysis model based on the input variables contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitcdiscr(Tbl,Y)` returns a fitted discriminant analysis model based on the input variables contained in the table `Tbl` and response `Y`.

`Mdl = fitcdiscr(X,Y)` returns a discriminant analysis classifier based on the input variables `X` and response `Y`.

`Mdl = fitcdiscr(____,Name,Value)` fits a classifier with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can optimize hyperparameters to minimize the model's cross-validation loss, or specify the cost of misclassification, the prior probabilities for each class, or the observation weights.

Examples

Train Discriminant Analysis Model

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis model using the entire data set.

```
Mdl = fitcdiscr(meas,species)
```

```
Mdl =
```

```
ClassificationDiscriminant
    ResponseName: 'Y'
  CategoricalPredictors: []
        ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
  NumObservations: 150
    DiscrimType: 'linear'
           Mu: [3×4 double]
          Coeffs: [3×3 struct]
```

Mdl is a `ClassificationDiscriminant` model. To access its properties, use dot notation. For example, display the group means for each predictor.

```
Mdl.Mu
```

```
ans =
```

```
    5.0060    3.4280    1.4620    0.2460
    5.9360    2.7700    4.2600    1.3260
    6.5880    2.9740    5.5520    2.0260
```

To predict labels for new observations, pass Mdl and predictor data to `predict`.

Optimize Discriminant Analysis Model

This example shows how to optimize hyperparameters automatically using `fitcdiscr`. The example uses Fisher's iris data.

Load the data.

```
load fisheriris
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng(1)
Mdl = fitcdiscr(meas,species,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',...
    struct('AcquisitionFunctionName','expected-improvement-plus'))
```

30	Accept	0.02	0.13933	0.02	0.02016	0.00018042

Optimization completed.

MaxObjectiveEvaluations of 30 reached.

Total function evaluations: 30

Total elapsed time: 53.0555 seconds.

Total objective function evaluation time: 5.4485

Best observed feasible point:

Delta	Gamma
0.43465	0.019285

Observed objective function value = 0.02

Estimated objective function value = 0.02016

Function evaluation time = 0.15794

Best estimated feasible point (according to models):

Delta	Gamma
2.06e-06	0.015157

Estimated objective function value = 0.02016

Estimated function evaluation time = 0.17565

Mdl =

ClassificationDiscriminant

```

      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
      NumObservations: 150

```

```
HyperparameterOptimizationResults: [1×1 BayesianOptimization]  
  DiscrimType: 'linear'  
    Mu: [3×4 double]  
  Coeffs: [3×3 struct]
```

The fit achieved about 2% loss for the default 5-fold cross validation.

Input Arguments

Tb1 — Sample data
table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element must correspond to one row of the array.

It is good practice to specify the order of the classes using the `ClassNames` name-value pair argument.

Data Types: `char`

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of `'Y-X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char`

Y – Class labels

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X`.

The software considers `NaN`, `''` (empty character vector), and `<undefined>` values in `Y` to be missing values. Consequently, the software does not train using observations with a missing response.

Data Types: `single` | `double` | `logical` | `char` | `cell`

X – Predictor data

numeric matrix

Predictor values, specified as a numeric matrix. Each column of `X` represents one variable, and each row represents one observation.

`fitcdiscr` considers `NaN` values in `X` as missing values. `fitcdiscr` does not use observations with missing values for `X` in the fit.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note: You cannot use any cross-validation name-value pair along with `OptimizeHyperparameters`. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair.

Example: 'DiscrimType', 'quadratic', 'SaveMemory', 'on' specifies a quadratic discriminant classifier and does not store the covariance matrix in the output object.

Model Parameters

'ClassNames' — Names of classes to use for training

categorical array | cell array of character vectors | character array | logical vector | numeric vector

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical or character array, logical or numeric vector, or cell array of character vectors. **ClassNames** must be the same data type as **Y**.

If **ClassNames** is a character array, then each element must correspond to one *row* of the array.

Use **ClassNames** to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use **ClassNames** to specify the order of the dimensions of **Cost** or the column order of classification scores returned by **predict**.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in **Y** is {'a', 'b', 'c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default is the set of all distinct class names in **Y**.

Example: 'ClassNames', {'b', 'g'}

Data Types: categorical | char | logical | single | double | cell

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where **Cost**(*i*, *j*) is the cost of classifying a point into class *j* if its true class is *i* (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of **Cost**, additionally specify the **ClassNames** name-value pair argument.

- Structure **S** having two fields: **S.ClassNames** containing the group names as a variable of the same type as **Y**, and **S.ClassificationCosts** containing the cost matrix.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Data Types: single | double | struct

'FillCoeffs' — Coeffs property flag

'on' | 'off'

Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and 'on' or 'off'. Setting the flag to 'on' populates the **Coeffs** property in the classifier object. This can be computationally intensive, especially when cross validating. The default is 'on', unless you specify a cross validation name-value pair, in which case the flag is set to 'off' by default.

Example: 'FillCoeffs', 'off'

'PredictorNames' — Predictor variable names

cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply **X** and **Y**, then you can use 'PredictorNames' to give the predictor variables in **X** names.
 - The order of the names in **PredictorNames** must correspond to the column order of **X**. That is, **PredictorNames{1}** is the name of **X(:,1)**, **PredictorNames{2}** is the name of **X(:,2)**, and so on. Also, **size(X,2)** and **numel(PredictorNames)** must be equal.
 - By default, **PredictorNames** is {**x1,x2,...**}.
- If you supply **Tbl**, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, **fitcdiscr** uses the predictor variables in **PredictorNames** and the response only in training.
 - **PredictorNames** must be a subset of **Tbl.Properties.VariableNames** and cannot include the name of the response variable.
 - By default, **PredictorNames** contains the names of all predictor variables.

- It good practice to specify the predictors for training using one of 'PredictorNames' or formula only.

```
Example: 'PredictorNames',
{'SepalLength', 'SepalWidth', 'PedalLength', 'PedalWidth'}
```

Data Types: cell

'Prior' — Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in Y .
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	A structure <code>S</code> with two fields: <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as Y. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

```
Example: 'Prior', 'uniform'
```

Data Types: `single` | `double` | `struct`

'ResponseName' — Response variable name

'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName', 'response'

Data Types: `char`

'SaveMemory' — Flag to save covariance matrix

'off' (default) | 'on'

Flag to save covariance matrix, specified as the comma-separated pair consisting of 'SaveMemory' and either 'on' or 'off'. If you specify 'on', then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify 'off', then `fitcdiscr` computes and stores the full covariance matrix in `Mdl`.

Specify `SaveMemory` as 'on' when the input matrix contains thousands of predictors.

Example: 'SaveMemory', 'on'

'ScoreTransform' — Score transform function

'none' (default) | character vector | function handle

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a function handle or value in this table.

Value	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.

Value	Formula
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: function_handle | char

'Weights' — Observation weights

numeric vector of positive values | character vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as 'W'. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n, 1)`, where n is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char`

Cross-Validation

'CrossVal' — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross validate later by passing `Mdl` to `crossval`.

Example: 'CrossVal', 'on'

'CVPartition' — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data

- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify, e.g., `'KFold', k`, then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold', 5`

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout', 'on'`, then, for each of the n observations, where n is `size(Mdl.X, 1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Leaveout', 'on'

Data Types: char

Hyperparameters

'Delta' — Linear coefficient threshold

0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of 'Delta' and a nonnegative scalar value. If a coefficient of `Mdl` has magnitude smaller than `Delta`, `Mdl` sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be 0 for quadratic discriminant models.

Data Types: single | double

'DiscrimType' — Discriminant type

'linear' (default) | 'quadratic' | 'diagLinear' | 'diagQuadratic' | 'pseudoLinear' | 'pseudoQuadratic'

Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and a character vector in this table.

Value	Description	Predictor Covariance Treatment
'linear'	Regularized linear discriminant analysis (LDA)	<ul style="list-style-type: none"> All classes have the same covariance matrix. $\hat{\Sigma}_\gamma = (1 - \gamma)\hat{\Sigma} + \gamma \text{diag}(\hat{\Sigma})$. <p>$\hat{\Sigma}$ is the empirical, pooled covariance matrix and γ is the amount of regularization.</p>
'diaglinear'	LDA	All classes have the same, diagonal covariance matrix.
'pseudolinear'	LDA	All classes have the same covariance matrix. The software inverts the

Value	Description	Predictor Covariance Treatment
		covariance matrix using the pseudo inverse.
'quadratic'	Quadratic discriminant analysis (QDA)	The covariance matrices can vary among classes.
'diagquadratic'	QDA	The covariance matrices are diagonal and can vary among classes.
'pseudoquadratic'	QDA	The covariance matrices can vary among classes. The software inverts the covariance matrix using the pseudo inverse.

Note: To use regularization, you must specify 'linear'. To specify the amount of regularization, use the **Gamma** name-value pair argument.

Example: 'DiscrimType', 'quadratic'

'Gamma' — Amount of regularization

scalar value in the interval [0,1]

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the interval [0,1]. **Gamma** provides finer control over the covariance matrix structure than **DiscrimType**.

- If you specify 0, then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.
 - For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the covariance matrix. You can display the chosen regularization amount by entering `Mdl.Gamma` at the command line.
 - For quadratic discriminant analysis, if at least one class has an empirical covariance matrix that is singular, then the software throws an error.

- If you specify a value in the interval (0,1), then you must implement linear discriminant analysis, otherwise the software throws an error. Consequently, the software sets `DiscrimType` to `'linear'`.
- If you specify 1, then the software uses maximum regularization for covariance matrix estimation. That is, the software restricts the covariance matrix to be diagonal. Alternatively, you can set `DiscrimType` to `'diagLinear'` or `'diagQuadratic'` for diagonal covariance matrices.

Example: `'Gamma', 1`

Data Types: `single` | `double`

Hyperparameter Optimization

'OptimizeHyperparameters' — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'Delta', 'Gamma'}`
- `'all'` — Optimize all eligible parameters.
- Cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitcdiscr` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 29-3219. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note: `OptimizeHyperparameters` values override any values you set using other name-value pairs. For example, setting `OptimizeHyperparameters` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitcdiscr` are:

- **Delta** — `fitcdiscr` searches among positive values, by default log-scaled in the range `[1e-6,1e3]`.
- **DiscrimType** — `fitcdiscr` searches among `'linear'`, `'quadratic'`, `'diagLinear'`, `'diagQuadratic'`, `'pseudoLinear'`, and `'pseudoQuadratic'`.
- **Gamma** — `fitcdiscr` searches among real values in the range `[0,1]`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcdiscr',meas,species);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression, and the misclassification rate for classification. To control the iterative display, set the `HyperparameterOptimizationOptions` name-value pair, `Verbose` field. To control the plots, set the `HyperparameterOptimizationOptions` name-value pair, `ShowPlots` field.

For an example, see “Optimize Discriminant Analysis Model” on page 29-1837.

Example: `'auto'`

Data Types: `char` | `cell`

'HyperparameterOptimizationOptions' — Options for optimization

structure

Options for optimization, specified as a structure. Modifies the effect of the `OptimizeHyperparameters` name-value pair. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> • <code>'bayesopt'</code> — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. • <code>'gridsearch'</code> — Use grid search with <code>NumGridDivisions</code> values per dimension. 	<code>'bayesopt'</code>

Field Name	Values	Default
	<ul style="list-style-type: none"> 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the <code>commandsortrows(Mdl.ParameterOptim.</code></p>	
AcquisitionFunction	<ul style="list-style-type: none"> 'expected-improvement-per-second-plus' 'expected-improvement' 'expected-improvement-plus' 'expected-improvement-per-second' 'lower-confidence-bound' 'probability-of-improvement' <p>For details, see the <code>bayesopt</code> <code>AcquisitionFunctionName</code> name-value pair, or “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
NumGridDivisions	For 'gridsearch', the number of values in each dimension. Can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. Ignored for categorical variables.	10

Field Name	Values	Default
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , plots the best objective function value against iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is <code>'bayesopt'</code> , then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediate	Logical value indicating whether to save results when <code>Optimizer</code> is <code>'bayesopt'</code> . If <code>true</code> , overwrites a workspace variable named <code>'BayesoptResults'</code> at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesoptVerbose</code> name-value pair.	1
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <p><code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.</p>	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code>	<code>Kfold = 5</code>

Field Name	Values	Default
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example: `struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

Mdl — Trained discriminant analysis classification model

`ClassificationDiscriminant` model object | `ClassificationPartitionedModel` cross-validated model object

Trained discriminant analysis classification model, returned as a `ClassificationDiscriminant` model object or a `ClassificationPartitionedModel` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedModel` cross-validated model object. Otherwise, `Mdl` is a `ClassificationDiscriminant` model object.

To reference properties of `Mdl`, use dot notation. For example, to display the estimated component means at the Command Window, enter `Mdl.Mu`.

Definitions

Discriminant Classification

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model assumes X has a Gaussian mixture distribution (`gmdistribution`).
- For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.

- For quadratic discriminant analysis, both means and covariances of each class vary.

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1, \dots, K} \sum_{k=1}^K \hat{P}(k | x) C(y | k),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(k | x)$ is the posterior probability of class k for observation x .
- $C(y | k)$ is the cost of classifying an observation as y when its true class is k .

For details, see “How the `predict` Method Classifies” on page 17-6.

Alternative Functionality

Functions

The `classify` function also performs discriminant analysis. `classify` is usually more awkward to use.

- `classify` requires you to fit the classifier every time you make a new prediction.
- `classify` does not perform cross validation or hyperparameter optimization.
- `classify` requires you to fit the classifier when changing prior probabilities.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Tall Arrays

This function supports tall arrays for out-of-memory data with some limitations.

- Supported name-value pairs are:
 - 'ClassNames'
 - 'Cost'
 - 'DiscrimType'
 - 'PredictorNames'
 - 'Prior'
 - 'ResponseName'
 - 'ScoreTransform'
 - 'Weights'
- For tall arrays and tall tables, `fitcdiscr` returns a `CompactClassificationDiscriminant` object, which contains most of the same properties as a `ClassificationDiscriminant` object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these `ClassificationDiscriminant` properties:
 - `ModelParameters`
 - `NumObservations`
 - `ParameterOptimizationResults`
 - `RowsUsed`
 - `XCentered`
 - `W`
 - `X`
 - `Y`

Additionally, the compact object does not support these `ClassificationDiscriminant` methods:

- `compact`
- `crossval`

- `cvshrink`
- `resubEdge`
- `resubLoss`
- `resubMargin`
- `resubPredict`

For more information, see “Tall Arrays” (MATLAB).

Topics

“Discriminant Analysis” on page 17-3

Introduced in R2014a

fitcecoc

Fit multiclass models for support vector machines or other classifiers

Syntax

```
Mdl = fitcecoc(Tbl,ResponseVarName)
```

```
Mdl = fitcecoc(Tbl,formula)
```

```
Mdl = fitcecoc(Tbl,Y)
```

```
Mdl = fitcecoc(X,Y)
```

```
Mdl = fitcecoc( ____,Name,Value)
```

```
[Mdl,HyperparameterOptimizationResults] = fitcecoc( ____,Name,Value)
```

Description

`Mdl = fitcecoc(Tbl,ResponseVarName)` returns a full, trained, multiclass, error-correcting output codes (ECOC) model using the predictors in table `Tbl` and the class labels in `Tbl.ResponseVarName`. `fitcecoc` uses $K(K-1)/2$ binary support vector machine (SVM) models using the one-versus-one coding design, where K is the number of unique class labels (levels). `Mdl` is a `ClassificationECOC` model.

`Mdl = fitcecoc(Tbl,formula)` returns an ECOC model using the predictors in table `Tbl` and the class labels. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used for training.

`Mdl = fitcecoc(Tbl,Y)` returns an ECOC model using the predictors in table `Tbl` and the class labels in vector `Y`.

`Mdl = fitcecoc(X,Y)` returns a full, trained ECOC model using the predictors `X` and the class labels `Y`.

`Mdl = fitcecoc(____,Name,Value)` returns an ECOC model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes.

For example, specify different binary learners, a different coding design, or to cross-validate. It is good practice to cross-validate using the `Kfold Name, Value` pair argument. The cross-validation results determine how well the model generalizes.

```
[Mdl,HyperparameterOptimizationResults] = fitcecoc( ____,  
Name,Value) also returns hyperparameter optimization details when you pass an  
OptimizeHyperparameters name-value pair with Learners = 'linear'. For other  
Learners, the HyperparameterOptimizationResults property of Mdl contains the  
results.
```

Examples

Train Multiclass Model Using SVM Learners

Train an error-correcting output codes (ECOC) multiclass model using support vector machine (SVM) binary learners.

Load Fisher's iris data set.

```
load fisheriris  
X = meas;  
Y = species;
```

Train an ECOC multiclass model using the default options.

```
Mdl = fitcecoc(X,Y)
```

```
Mdl =
```

```
ClassificationECOC  
    ResponseName: 'Y'  
    CategoricalPredictors: []  
          ClassNames: {'setosa' 'versicolor' 'virginica'}  
    ScoreTransform: 'none'  
    BinaryLearners: {3×1 cell}  
    CodingName: 'onevsone'
```

`Mdl` is a `ClassificationECOC` model. By default, `fitcecoc` uses SVM binary learners, and uses a one-versus-one coding design. You can access `Mdl` properties using dot notation.

Display the coding design matrix.

```
Mdl.ClassNames
CodingMat = Mdl.CodingMatrix
```

```
ans =

3x1 cell array

'setosa'
'versicolor'
'virginica'
```

```
CodingMat =

     1     1     0
    -1     0     1
     0    -1    -1
```

A one-versus-one coding design on three classes yields three binary learners. Columns of `CodingMat` correspond to learners, and rows correspond to classes. The class order corresponds to the order in `Mdl.ClassNames`. For example, `CodingMat(:,1)` is `[1; -1; 0]` and indicates that the software trains the first SVM binary learner using all observations classified as 'setosa' and 'versicolor'. Since 'setosa' corresponds to 1, it is the positive class, and since 'versicolor' corresponds to -1, it is the negative class.

You can access each binary learner using cell indexing and dot notation.

```
Mdl.BinaryLearners{1}           % The first binary learner
```

```
ans =

classreg.learning.classif.CompactClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: [-1 1]
    ScoreTransform: 'none'
            Beta: [4x1 double]
            Bias: 1.4505
```

```
KernelParameters: [1×1 struct]
```

Compute the in-sample classification error.

```
isLoss = resubLoss(Mdl)
```

```
isLoss =
```

```
0.0067
```

The classification error is small, but the classifier might have been overfit. You can cross-validate the classifier using `CROSSVAL`.

Cross-Validate ECOC Classifier

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1)
```

```
t =
```

Fit template for classification SVM.

```
Alpha: [0×1 double]
BoxConstraint: []
CacheSize: []
CachingMethod: ''
ClipAlphas: []
DeltaGradientTolerance: []
Epsilon: []
GapTolerance: []
KKTolerance: []
IterationLimit: []
```

```

    KernelFunction: ''
    KernelScale: []
    KernelOffset: []
    KernelPolynomialOrder: []
    NumPrint: []
    Nu: []
    OutlierFraction: []
    RemoveDuplicates: []
    ShrinkagePeriod: []
    Solver: ''
    StandardizeData: 1
    SaveSupportVectors: []
    VerbosityLevel: []
    Version: 2
    Method: 'SVM'
    Type: 'classification'

```

`t` is an SVM template. All of its properties are empty, except for `StandardizeData`, `Method`, and `Type`. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier. It is good practice to specify the class order.

```

Mdl = fitcecoc(X,Y,'Learners',t,...
    'ClassNames',{'setosa','versicolor','virginica'});

```

`Mdl` is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Cross-validate `Mdl` using 10-fold cross-validation.

```

CVMdl = crossval(Mdl);

```

`CVMdl` is a `ClassificationPartitionedECOC` cross-validated ECOC classifier.

Estimate the generalization error.

```

oosLoss = kfoldLoss(CVMdl)

```

```

oosLoss =

```

```

    0.0400

```

The out-of-sample classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

Estimate Posterior Probabilities Using ECOC Classifiers

Load Fisher's iris data set. Train the classifier using the petal dimensions as predictors.

```
load fisheriris
X = meas(:,3:4);
Y = species;
rng(1); % For reproducibility
```

Create an SVM template, and specify the Gaussian kernel. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by `predict` or `resubPredict`) using the 'FitPosterior' name-value pair argument. Display diagnostic messages during the training using the 'Verbose' name-value pair argument. It is good practice to specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',1,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'Verbose',2);
```

```
Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 2
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 1 (SVM).
Training binary learner 2 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 3
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 2 (SVM).
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 3
Positive class indices: 2
```

```
Fitting posterior probabilities for learner 3 (SVM).
```

Mdl is a `ClassificationECOC` model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the in-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities using the `'Verbose'` name-value pair argument.

```
[label,~,~,Posterior] = resubPredict(Mdl,'Verbose',1);
Mdl.BinaryLoss
```

```
Predictions from all learners have been computed.
Loss for all observations has been computed.
Computing posterior probabilities...
```

```
ans =
```

```
    'quadratic'
```

The software assigns an observation to the class that yields the smallest average binary loss. Since all binary learners are computing posterior probabilities, the binary loss function is `quadratic`.

Display a random set of results.

```
idx = randsample(size(X,1),10,1);
Mdl.ClassNames
table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

```
ans =
```

```
3×1 cell array
    'setosa'
    'versicolor'
    'virginica'
```

```
ans =
```

```
10×3 table
```

TrueLabel	PredLabel	Posterior		
'virginica'	'virginica'	0.0039321	0.0039869	0.99208
'virginica'	'virginica'	0.017067	0.018263	0.96467
'virginica'	'virginica'	0.014948	0.015856	0.9692
'versicolor'	'versicolor'	2.2197e-14	0.87317	0.12683
'setosa'	'setosa'	0.999	0.00025091	0.00074639
'versicolor'	'virginica'	2.2195e-14	0.059429	0.94057
'versicolor'	'versicolor'	2.2194e-14	0.97001	0.029986
'setosa'	'setosa'	0.999	0.0002499	0.00074741
'versicolor'	'versicolor'	0.0085646	0.98259	0.008849
'setosa'	'setosa'	0.999	0.00025013	0.00074718

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);

x1Pts = linspace(xMin(1),xMax(1));
x2Pts = linspace(xMin(2),xMax(2));
[x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts);

[~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

```
figure;
contourf(x1Grid,x2Grid,...
         reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.YLabel.String = 'Maximum posterior';
h.YLabel.FontSize = 15;
hold on
gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8);
gh(2).LineWidth = 2;
gh(3).LineWidth = 2;

title 'Iris Petal Measurements and Maximum Posterior';
xlabel 'Petal length (cm)';
```

```

ylabel 'Petal width (cm)';
axis tight
legend(gh, 'Location', 'NorthWest')
hold off

```

Train Multiclass Linear Classification Model

Train an ECOC model composed of multiple binary, linear classification models.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

Create a default linear-classification-model template.

```
t = templateLinear();
```

To adjust the default values, see `templateLinear`.

Train an ECOC model composed of multiple binary, linear classification models that can identify the product given the frequency distribution of words on a documentation web page. For faster training time, transpose the predictor data, and specify that observations correspond to columns.

```
X = X';  
rng(1); % For reproducibility  
Mdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns')
```

```
Mdl =
```

```
classreg.learning.classif.CompactClassificationECOC  
  ResponseName: 'Y'  
  ClassNames: [1×13 categorical]  
  ScoreTransform: 'none'  
  BinaryLearners: {78×1 cell}  
  CodingMatrix: [13×78 double]
```

Alternatively, you can train an ECOC model composed of default linear classification models using `'Learners','Linear'`.

To conserve memory, `fitcecoc` returns trained ECOC models composed of linear classification learners in `CompactClassificationECOC` model objects.

Train ECOC Classifiers Using Ensembles and Parallel Computing

Train a one-versus-all ECOC classifier using a GentleBoost ensemble of decision trees with surrogate splits. Estimate the classification error using 10-fold cross-validation.

Load and inspect the `arrhythmia` data set.

```
load arrhythmia  
[n,p] = size(X)  
isLabels = unique(Y);  
nLabels = numel(isLabels)
```

```
tabulate(categorical(Y))  
n =  
  452  
  
p =  
  279  
  
nLabels =  
  13  
  
  Value    Count    Percent  
  1      245    54.20%  
  2       44     9.73%  
  3       15     3.32%  
  4       15     3.32%  
  5       13     2.88%  
  6       25     5.53%  
  7        3     0.66%  
  8        2     0.44%  
  9        9     1.99%  
 10       50    11.06%  
 14        4     0.88%  
 15        5     1.11%  
 16       22     4.87%
```

There are 279 predictors, and a relatively small sample size of 452. There are 16 distinct labels, but only 13 are represented in the response (Y), and each label describes various degrees of arrhythmia. 54.20% of the observations are in class 1.

Create an ensemble template. You must specify at least three arguments: a method, a number of learners, and the type of learner. For this example, specify 'GentleBoost' for the method, 100 for the number of learners, and a decision tree template that uses surrogate splits since there are missing observations.

```
tTree = templateTree('surrogate','on');  
tEnsemble = templateEnsemble('GentleBoost',100,tTree);
```

tEnsemble is a template object. Most of its properties are empty, but the software fills them with their default values during training.

Train a one-versus-all ECOC classifier using the ensembles of decision trees as binary learners. If you have a Parallel Computing Toolbox license, then you can speed up the computation by specifying to use parallel computing. This sends each binary learner to a worker in the pool (the number of workers depends on your system configuration). Also, specify that the prior probabilities are $1/K$, where $K = 13$, which is the number of distinct classes.

```
pool = parpool; % Invoke workers
options = statset('UseParallel',1);
Mdl = fitcecoc(X,Y,'Coding','onevsall','Learners',tEnsemble,...
    'Prior','uniform','Options',options);
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 2 workers.

Mdl is a ClassificationECOC model.

Cross-validate the ECOC classifier using 10-fold cross-validation.

```
CVMD1 = crossval(Mdl,'Options',options);
```

Warning: One or more folds do not contain points from all the groups.

CVMD1 is a ClassificationPartitionedECOC model. The warning indicates that some classes are not represented while the software trains at least one fold. Therefore, those folds cannot predict labels for the missing classes. You can inspect the results of a fold using cell indexing and dot notation, e.g., access the results of the first fold by entering CVMD1.Trained{1}. Your results might vary.

Use the cross-validated ECOC classifier to predict out-of-fold labels. You can compute the confusion matrix using `confusionmat`. However, if you have a Neural Network Toolbox license, you can plot the confusion matrix using `plotconfusion`. The input arguments of `plotconfusion` are not vectors of the true and predicted labels like `confusionmat`, but indicator matrices of the true and predicted labels. Both start as K -by- n matrices of 0s. If observation j has label index k (or has predicted label k), then element (k,j) of the true label indicator matrix (or predicted label indicator matrix) is 1. You can convert label indices returned by `predict`, `resubPredict`, or `kfoldPredict` to label indicator matrices using linear indexing. For details on linear indexing, see `sub2ind` and `ind2sub`.

```
oofLabel = kfoldPredict(CVMD1,'Options',options);
ConfMat = confusionmat(Y,oofLabel);
```

```
% Convert the integer label vector to a class-identifier matrix.
[~,grpOOF] = ismember(oofLabel,isLabels);
```

```
oofLabelMat = zeros(nLabels,n);
idxLinear = sub2ind([nLabels n],grpOOF,(1:n)');
oofLabelMat(idxLinear) = 1; % Flags the row corresponding to the class
[~,grpY] = ismember(Y,isLabels);
YMat = zeros(nLabels,n);
idxLinearY = sub2ind([nLabels n],grpY,(1:n)');
YMat(idxLinearY) = 1;

figure;
plotconfusion(YMat,oofLabelMat);
h = gca;
h.XTickLabel = [num2cell(isLabels); {' '}];
h.YTickLabel = [num2cell(isLabels); {' '}];
```

Optimize ECOC Classifier

This example shows how to optimize hyperparameters automatically using `fitcecoc`. The example uses Fisher's iris data.

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng default
Mdl = fitcecoc(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
    'expected-improvement-plus'))
```

- “Quick Start Parallel Computing for Statistics and Machine Learning Toolbox” on page 27-2

Input Arguments

Tbl — Sample data

table

Sample data, specified as a table. Each row of **Tbl** corresponds to one observation, and each column corresponds to one predictor. Optionally, **Tbl** can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not accepted.

If **Tbl** contains the response variable, and you want to use all remaining variables in **Tbl** as predictors, then specify the response variable using **ResponseVarName**.

If **Tbl** contains the response variable, and you want to use only a subset of the remaining variables in **Tbl** as predictors, specify a formula using **formula**.

If **Tbl** does not contain the response variable, specify a response variable using **Y**. The length of response variable and the number of **Tbl** rows must be equal.

Note: For training linear classification models, **fitcecoc** does not support tables. That is, if **Learners** is 'linear' or contains a linear classification model learner template (see **templateLinear**), you cannot supply **Tbl**, **ResponseVarName**, or **formula**. Supply a matrix of predictor data (**X**) and an array of responses (**Y**) instead.

Data Types: table

ResponseVarName — Response variable name

name of variable in **Tbl**

Response variable name, specified as the name of a variable in **Tbl**.

You must specify **ResponseVarName** as a character vector. For example, if the response variable **Y** is stored as **Tbl.Y**, then specify it as 'Y'. Otherwise, the software treats all columns of **Tbl**, including **Y**, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If **Y** is a character array, then each element must correspond to one row of the array.

It is good practice to specify the order of the classes using the `ClassNames` name-value pair argument.

Data Types: `char`

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of 'Y-X1+X2+X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a `formula`. If you specify a `formula`, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels to which the ECOC model is trained, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

If Y is a character array, then each element must correspond to one row of the array.

The length of Y and the number of rows of `Tbl` or X must be equal.

It is good practice to specify the class order using the `ClassNames` name-value pair argument.

Data Types: `char` | `cell` | `categorical` | `logical` | `single` | `double`

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as a full or sparse matrix.

The length of Y and the number of observations in X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the `PredictorNames` name-value pair argument.

Note:

- For linear classification learners, if you orient `X` so that observations correspond to columns and specify `'ObservationsIn'`, `'columns'`, then you can experience a significant reduction in optimization-execution time.
 - For all other learners, orient `X` so that observations correspond to rows.
 - `fitcecoc` supports sparse matrices for training linear classification models only.
-

Data Types: `double` | `single`

Note: The software treats NaN, empty character vector (`' '`), and `<undefined>` elements as missing data. The software removes rows of `X` corresponding to missing values in `Y`. However, the treatment of missing values in `X` varies among binary learners. For details, see the training functions for your binary learners: `fitcdiscr`, `fitcknn`, `fitclinear`, `fitcnb`, `fitcsvm`, `fitctree`, or `fitensemb`. Removing observations decreases the effective training or cross-validation sample size.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, `...`, `NameN`, `ValueN`.

Note: You cannot use any cross-validation name-value pair along with `OptimizeHyperparameters`. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair.

Example: `'Learners','tree','Coding','onevsone','CrossVal','on'` specifies to use decision trees for all binary learners, a one-versus-one coding design, and to implement 10-fold cross-validation.

ECOC Classifier Options

'Coding' – Coding design

'onevsone' (default) | 'allpairs' | 'binarycomplete' | 'denserandom' | 'onevsall' | 'ordinal' | 'sparserandom' | 'ternarycomplete' | numeric matrix

Coding design name, specified as the comma-separated pair consisting of 'Coding' and a numeric matrix or a value in this table.

Value	Number of Binary Learners	Description
'allpairs' and 'onevsone'	$K(K-1)/2$	For each binary learner, one class is positive, another is negative, and the software ignores the rest. This design exhausts all combinations of class pair assignments.
'binarycomplete'	$2^{(K-1)} - 1$	This design partitions the classes into all binary combinations, and does not ignore any classes. For each binary learner, all class assignments are -1 and 1 with at least one positive and negative class in the assignment.
'denserandom'	Random, but approximately $10 \log_2 K$	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 29-1910.
'onevsall'	K	For each binary learner, one class is positive and the rest are negative. This design

Value	Number of Binary Learners	Description
		exhausts all combinations of positive class assignments.
'ordinal'	$K - 1$	For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, the rest positive, and so on.
'sparserandom'	Random, but approximately $15 \log_2 K$	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 29-1910.
'ternarycomplete'	$(3^K - 2^{(K+1)} + 1) / 2$	This design partitions the classes into all ternary combinations. All class assignments are 0, -1, and 1 with at least one positive and one negative class in the assignment.

You can also specify a coding design using a custom coding matrix. The custom coding matrix is a K -by- L matrix. Each row corresponds to a class and each column corresponds to a binary learner. The class order (rows) corresponds to the order in `ClassNames`. Compose the matrix by following these guidelines:

- Every element of the custom coding matrix must be -1, 0, or 1, and the value must correspond to a dichotomous class assignment. This table describes the meaning of `Coding(i, j)`, that is, the class that learner j assigns to observations in class i .

Value	Dichotomous Class Assignment
-1	Negative class

Value	Dichotomous Class Assignment
0	Before training, learner j removes observations in class i from the data set.
1	Positive class

- Every column must contain at least one -1 or 1.
- For all column indices i, j such that $i \neq j$, `Coding(:, i)` cannot equal `Coding(:, j)` and `Coding(:, i)` cannot equal `-Coding(:, j)`.
- All rows of the custom coding matrix must be different.

For more details on the form of custom coding design matrices, see “Custom Coding Design Matrices” on page 29-1908.

Example: `'Coding', 'ternarycomplete'`

Data Types: `char | double | single | int16 | int32 | int64 | int8`

'FitPosterior' — Flag indicating whether to transform scores to posterior probabilities
false or 0 (default) | true or 1

Flag indicating whether to transform scores to posterior probabilities, specified as the comma-separated pair consisting of `'FitPosterior'` and a true (1) or false (0).

If `FitPosterior` is true, then the software transforms binary-learner classification scores to posterior probabilities. You can obtain posterior probabilities by using `kfoldPredict`, `predict`, or `resubPredict`.

`fitcecoc` does not support fitting posterior probabilities:

- For the ensemble methods `AdaBoostM2`, `LPBoost`, `RUSBoost`, `RobustBoost`, and `TotalBoost`.
- If the binary learners (`Learners`) are linear classification models that implement SVM. To obtain posterior probabilities for linear classification models, implement logistic regression instead.

Example: `'FitPosterior', true`

Data Types: `logical`

'Learners' — Binary learner templates

`'svm'` (default) | `'discriminant'` | `'knn'` | `'linear'` | `'naivebayes'` | `'tree'` |
template object | cell vector of template objects

Binary learner templates, specified as the comma-separated pair consisting of 'Learners' and a character vector, template object, or cell vector of template objects. Specifically, you can specify binary classifiers such as SVM, and the ensembles that use GentleBoost, LogitBoost, and RobustBoost, to solve multiclass problems. However, `fitcecoc` also supports multiclass models as binary classifiers.

- If **Learners** is a character vector, then the software trains each binary learner using the default values of the specified algorithm. This table summarizes the available algorithms.

Value	Description
'discriminant'	Discriminant analysis. For default options, see <code>templateDiscriminant</code> .
'knn'	k -nearest neighbors. For default options, see <code>templateKNN</code> .
'linear'	Linear classification model. For default options, see <code>templateLinear</code> .
'naivebayes'	Naive Bayes. For default options, see <code>templateNaiveBayes</code> .
'svm'	SVM. For default options, see <code>templateSVM</code> .
'tree'	Classification trees. For default options, see <code>templateTree</code> .

- If **Learners** is a template object, then each binary learner trains according to the stored options. You can create a template object using:
 - `templateDiscriminant`, for discriminant analysis.
 - `templateEnsemble`, for ensemble learning. You must at least specify the learning method (Method), the number of learners (NLearn), and the type of learner (Learners). You cannot use the `AdaBoostM2` ensemble method for binary learning.
 - `templateKNN`, for k -nearest neighbors.
 - `templateLinear`, for linear classification.
 - `templateNaiveBayes`, for naive Bayes.
 - `templateSVM`, for SVM.
 - `templateTree`, for classification trees.

- If `Learners` is cell vector of template objects, then:
 - Cell j corresponds to binary learner j (in other words, column j of the coding design matrix), and the cell vector must have length L . L is the number of columns in the coding design matrix. For details, see [Coding](#).
 - To use one of the built-in loss functions for prediction, then all binary learners must return a score in the same range. For example, you cannot include default SVM binary learners with default naive Bayes binary learners. The former returns a score in the range $(-\infty, \infty)$, and the latter returns a posterior probability as a score. Otherwise, you must provide a custom loss as a function handle to functions such as `predict` and `loss`.
 - You cannot specify linear classification model learner templates with any other template in the cell array.

By default, the software trains learners using default SVM templates.

Example: `'Learners', 'tree'`

'ObservationsIn' — Predictor data observation dimension

`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as the comma-separated pair consisting of `'ObservationsIn'` and `'columns'` or `'rows'`.

Note:

- For linear classification learners, if you orient `X` so that observations correspond to columns and specify `'ObservationsIn', 'columns'`, then you can experience a significant reduction in optimization-execution time.
 - For all other learners, orient `X` so that observations correspond to rows.
-

'Verbose' — Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0, 1, or 2. `Verbose` controls the amount of diagnostic information per binary learner that the software displays in the Command Window.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display diagnostic information.
1	The software displays diagnostic messages every time it trains a new binary learner.
2	The software displays extra diagnostic messages every time it trains a new binary learner.

Example: `'Verbose', 1`

Data Types: `double` | `single`

Cross-Validation Options

'CrossVal' — Flag to train cross-validated classifier

`'off'` (default) | `'on'`

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using one of the `CVPartition`, `Holdout`, `KFold`, or `Leaveout` name-value pair arguments. You can only use one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: `'Crossval', 'on'`

Data Types: `char`

'CVPartition' — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Holdout', 0.1

Data Types: double | single

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'KFold', 5

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations, where n is `size(Mdl.X,1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in the cells of a n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Note: Leave-one-out is not recommended for cross-validating ECOC models composed of linear classification model learners.

Example: 'Leaveout', 'on'

Data Types: char

Other Classification Options

'CategoricalPredictors' — Categorical predictors list

character array | logical vector | numeric vector | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- A numeric vector with indices from 1 through p , where p is the number of columns of X .
- A logical vector of length p , where a `true` entry means that the corresponding column of X is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.

- 'all', meaning all predictors are categorical.

Specification of `CategoricalPredictors` is appropriate if:

- At least one predictor is categorical and all binary learners are classification trees, naive Bayes learners, SVM, or ensembles of classification trees.
- All predictors are categorical and at least one binary learner is k NN.

If you specify `CategoricalPredictors` for any other learner, then the software warns that it cannot train that binary learner. For example, the software cannot train linear classification model learners using categorical predictors.

By default, if the predictor data is in a matrix (`X`), the software assumes that none of the predictors are categorical. If the predictor data is in a table (`Tbl`), the software assumes that a variable is categorical if it contains, logical values, values of the unordered data type `categorical`, or a cell array of character vectors.

Example: `'CategoricalPredictors', 'all'`

Data Types: `single` | `double` | `char`

'ClassNames' — Names of classes to use for training

categorical array | cell array of character vectors | character array | logical vector | numeric vector

Names of classes to use for training, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` must be the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a', 'b', 'c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames', {'a', 'c'}`.

The default is the set of all distinct class names in Y .

Example: `'ClassNames', {'b', 'g'}`

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

'Cost' — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure. If you specify:

- The square matrix `Cost`, then `Cost(i, j)` is the cost of classifying a point into class j if its true class is i . That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- The structure `S`, then it must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as Y
 - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

The default is `ones(K) - eye(K)`, where K is the number of distinct classes.

Example: `'Cost', [0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double` | `single` | `struct`

'Options' — Parallel computing options

`[]` (default) | structure array returned by `statset`

Parallel computing options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`. These options require Parallel Computing Toolbox. `fitcecoc` uses `'Streams'`, `'UseParallel'`, and `'UseSubstreams'` fields.

This table summarizes the available options.

Option	Description
<code>'Streams'</code>	A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code> ,

Option	Description
	<p>the software uses the default stream or streams. If you specify <code>Streams</code>, use a single object except when the following are true:</p> <ul style="list-style-type: none"> • You have an open parallel pool. • <code>UseParallel</code> is true. • <code>UseSubstreams</code> is false. <p>In that case, use a cell array of the same size as the parallel pool. If a parallel pool is not open, then the software tries to open one (depending on your preferences), and <code>Streams</code> must supply a single random number stream.</p>
'UseParallel'	If you have Parallel Computing Toolbox, then you can invoke a pool of workers by setting <code>'UseParallel',1</code> .
'UseSubstreams'	Set to <code>true</code> to compute in parallel using the stream specified by <code>'Streams'</code> . Default is <code>false</code> . For example, set <code>Streams</code> to a type allowing substreams, such as <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code> .

A best practice to ensure more predictable results is to use `parpool` and explicitly create a parallel pool before you invoke parallel computing using `fitcecoc`.

Example: `'Options',statset('UseParallel',1)`

'PredictorNames' — Predictor variable names

cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `'PredictorNames'` to give the predictor variables in `X` names.

- The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
- By default, `PredictorNames` is `{x1,x2,...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitcecoc` uses the predictor variables in `PredictorNames` and the response only in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It good practice to specify the predictors for training using one of `'PredictorNames'` or `formula` only.

Example: `'PredictorNames'`,
`{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: cell

'Prior' — Prior probabilities

`'empirical'` (default) | `'uniform'` | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
<code>'empirical'</code>	The class prior probabilities are the class relative frequencies in <code>Y</code> .
<code>'uniform'</code>	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	A structure <code>S</code> with two fields:

Value	Description
	<ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

For more details on how the software incorporates class prior probabilities, see “Prior Probabilities and Cost” on page 29-1909.

Example: `struct('ClassNames',
{{'setosa','versicolor','virginica'}}, 'ClassProbs', 1:3)`

'ResponseName' — Response variable name

'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector.

- If you supply `Y`, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use 'ResponseName'.

Example: `'ResponseName', 'response'`

Data Types: char

'Weights' — Observation weights

numeric vector of positive values | character vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it

as 'W'. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n, 1)`, where n is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char`

Hyperparameter Optimization

'OptimizeHyperparameters' — Parameters to optimize

'none' (default) | 'auto' | 'all' | cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as:

- 'none' — Do not optimize.
- 'auto' — Use {'Coding'} along with the default parameters for the specified `Learners`:
 - `Learners = 'svm'` (default) — {'BoxConstraint', 'KernelScale'}
 - `Learners = 'discriminant'` — {'Delta', 'Gamma'}
 - `Learners = 'knn'` — {'Distance', 'NumNeighbors'}
 - `Learners = 'linear'` — {'Lambda', 'Learner'}
 - `Learners = 'naivebayes'` — {'DistributionNames', 'Width'}
 - `Learners = 'tree'` — {'MinLeafSize'}
- 'all' — Optimize all eligible parameters.
- Cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitcecoc` by varying the parameters. For information about cross-validation loss in a different context, see “Classification Loss” on page 29-3219. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note: OptimizeHyperparameters values override any values you set using other name-value pairs. For example, setting OptimizeHyperparameters to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitcecoc are:

- Coding — fitcecoc searches among 'onevsall' and 'onevsone'.
- The eligible hyperparameters for the chosen Learners:

Learners	Eligible Hyperparameters (Bold = Default)	Default Range
'discriminant'	Delta	Log-scaled in the range [1e-6, 1e3]
	DiscrimType	'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', and 'pseudoQuadratic'
	Gamma	Real values in [0, 1]
'knn'	Distance	'cityblock', 'chebychev', 'correlation', 'cosine', 'euclidean', 'hamming', 'jaccard', 'mahalanobis', 'minkowski', 'seuclidean', and 'spearman'
	DistanceWeight	'equal', 'inverse', and 'squaredinverse'
	Exponent	Positive values in [0.5, 3]
	NumNeighbors	Positive integer values log-scaled in the range [1, max(2, round(NumObservations/2))]
	Standardize	'true' and 'false'
'linear'	Lambda	Positive values log-scaled in the range [1e-5/NumObservations, 1e5/NumObservations]
	Learner	'svm' and 'logistic'

Learners	Eligible Hyperparameters (Bold = Default)	Default Range
	Regularization	'ridge' and 'lasso'
'naivebayes'	DistributionNames	'normal' and 'kernel'
	Width	Positive values log-scaled in the range [MinPredictorDiff/4,max(MaxPredictorRa
	Kernel	'normal', 'box', 'epanechnikov', and 'triangle'
'svm'	BoxConstraint	Positive values log-scaled in the range [1e-3,1e3]
	KernelScale	Positive values log-scaled in the range [1e-3,1e3]
	KernelFunction	'gaussian', 'linear', and 'polynomial'
	PolynomialOrder	Integers in the range [2,4]
	Standardize	'true' and 'false'
'tree'	MaxNumSplits	Integers log-scaled in the range [1,max(2,NumObservations-1)]
	MinLeafSize	Integers log-scaled in the range [1,max(2,floor(NumObservations/2))]
	NumVariablesToSample	Integers in the range [1,max(2,NumPredictors)]
	SplitCriterion	'gdi', 'deviance', and 'twoing'

Alternatively, use `hyperparameters` with your chosen Learners, such as

```
load fisheriris % hyperparameters requires data and learner
params = hyperparameters('fitcecoc',meas,species,'svm');
```

To see the eligible and default hyperparameters, examine `params`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
```

```
params = hyperparameters('fitcecoc',meas,species,'svm');
params(2).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression, and the misclassification rate for classification. To control the iterative display, set the `HyperparameterOptimizationOptions` name-value pair, `Verbose` field. To control the plots, set the `HyperparameterOptimizationOptions` name-value pair, `ShowPlots` field.

For an example, see “Optimize ECOC Classifier” on page 29-1874.

Example: 'auto'

Data Types: char | cell

'HyperparameterOptimizationOptions' — Options for optimization structure

Options for optimization, specified as a structure. Modifies the effect of the `OptimizeHyperparameters` name-value pair. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the <code>commandsortrows(Mdl.ParameterOptim</code></p>	'bayesopt'

Field Name	Values	Default
AcquisitionFunc	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>For details, see the <code>bayesopt</code> AcquisitionFunctionName name-value pair, or “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEva	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
NumGridDivision	For 'gridsearch', the number of values in each dimension. Can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. Ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , plots the best objective function value against iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is 'bayesopt', then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>

Field Name	Values	Default
SaveIntermediate	Logical value indicating whether to save results when <code>Optimizer</code> is 'bayesopt'. If <code>true</code> , overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a <code>BayesianOptimization</code> object.	false
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesoptVerbose</code> name-value pair.	1
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <p><code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.</p>	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code>	Kfold = 5
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example: `struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

Mdl1 — Trained ECOC model

ClassificationECOC model object | CompactClassificationECOC model object | ClassificationPartitionedECOC cross-validated model object | ClassificationPartitionedLinearECOC cross-validated model object

Trained ECOC classifier, returned as a `ClassificationECOC` or `CompactClassificationECOC` model object, or a `ClassificationPartitionedECOC` or `ClassificationPartitionedLinearECOC` cross-validated model object.

This table describes which types of model objects `fitcecoc` returns.

Linear Classification Model Learners?	Cross-Validation?	Returned model object
No	No	<code>ClassificationECOC</code>
No	Yes	<code>ClassificationPartitionedECOC</code>
Yes	No	<code>CompactClassificationECOC</code>
Yes	Yes	<code>ClassificationPartitionedLinearECOC</code>

HyperparameterOptimizationResults — Description of the cross-validation optimization of hyperparameters

BayesianOptimization object | table of hyperparameters and associated values

Description of the cross-validation optimization of hyperparameters, returned as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair was nonempty and `Learners` was `'linear'`. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`.
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observation from smallest (best) to highest (worst).

Data Types: `table`

Limitations

- For training linear classification models, `fitcecoc` does not support tables. That is, if `Learners` is 'linear' or contains a linear classification model learner template (see `templateLinear`), then you cannot supply `Tbl`, `ResponseVarName`, or `formula`. Supply a full or sparse matrix of predictor data (`X`) and an array of responses (`Y`) instead.
- `fitcecoc` supports sparse matrices for training linear classification models only. For all other models, supply a full matrix of predictor data instead.

Definitions

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the `LossFun` name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Coding Design

A *coding design* is a matrix where elements direct which classes are trained by each binary learner, that is, how the multiclass problem is reduced to a series of binary problems.

Each row of the coding design corresponds to a distinct class, and each column corresponds to a binary learner. In a ternary coding design (adopted by the software), for a particular column (or binary learner):

- Rows containing a 1 indicate to the binary learner to group all observations in the corresponding classes into a positive class.
- Rows containing a -1 indicate to the binary learner to group all observations in the corresponding classes into a negative class.
- Rows containing a 0 indicate to the binary learner to ignore all observations in the corresponding classes.

Coding matrices with large, minimal, pair-wise row distances based on the Hamming measure are desirable. For details on the pair-wise row distance measure, see “Random Coding Design Matrices” on page 29-1910 and [4].

This table describes popular coding designs. For the example, suppose K (the number of distinct classes) is 3.

Coding Design	Description	Number of Learners	Minimal Pair-Wise Row Distance
one-versus-all (OVA)	For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.	K	2
one-versus-one (OVO)	For each binary learner, one class is positive, another is negative, and the rest are ignored. This design exhausts all combinations of class pair assignments.	$K(K - 1)/2$	1
binary complete	This design partitions the classes	$2^{K-1} - 1$	2^{K-2}

Coding Design	Description	Number of Learners	Minimal Pair-Wise Row Distance
	into all binary combinations, and does not ignore any classes. That is, all class assignments are - 1 and 1 with at least one positive and negative class in the assignment for each binary learner.		
ternary complete	This design partitions the classes into all ternary combinations. That is, all class assignments are 0, - 1, and 1 with at least one positive and negative class in the assignment for each binary learner.	$(3^K - 2^{K+1} + 1)/2$	3^{K-2}
ordinal	For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, and the rest positive, and so on.	$K - 1$	1

Coding Design	Description	Number of Learners	Minimal Pair-Wise Row Distance
dense random	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 29-1910.	Random, but approximately $10 \log_2 K$	Variable
sparse random	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 29-1910.	Random, but approximately $15 \log_2 K$	Variable

This plot compares the number of binary learners for the coding designs with increasing K .

Error-Correcting Output Codes Model

An *error-correcting output codes (ECOC) model* reduces the problem of classification with three or more classes to a set of binary classifiers.

ECOC classification requires a coding design, which determines the classes that the binary learners train on, and a decoding scheme, which determines how the results (predictions) of the binary classifiers are aggregated.

Suppose that:

- There are three classes.
- The coding design is one-versus-one.

- The decoding scheme uses loss g .
- The learners are SVMs.

To build this classification model, ECOC follows these steps.

1

A one-versus-one coding design is

	Learner 1	Learner 2	Learner 3
Class 1	1	1	0
Class 2	-1	0	1
Class 3	0	-1	-1

Learner 1 trains on observations having Class 1 and Class 2, and treats Class 1 as the positive class and Class 2 as the negative class. The other learners are trained similarly. Let M be the coding design matrix with elements m_{kl} , and s_l be the predicted classification score for the positive class of learner l .

2

A new observation is assigned to the class (\hat{k}) that minimizes the aggregation of the losses for the L binary learners. That is,

$$\hat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{l=1}^L |m_{kl}| g(m_{kl}, s_l)}{\sum_{l=1}^L |m_{kl}|}.$$

ECOC models can improve classification accuracy, even compared to other multiclass models [2].

Tips

- The number of binary learners grows with the number of classes. For a problem with many classes, the `binarycomplete` and `ternarycomplete` coding designs are not efficient. However:
 - If $K \leq 4$, then use `ternarycomplete` coding design rather than `sparsrandom`.

- If $K \leq 5$, then use `binarycomplete` coding design rather than `denserandom`.

You can display the coding design matrix of a trained ECOC classifier by entering `Mdl.CodingMatrix` into the Command Window.

- You should form a coding matrix using intimate knowledge of the application, and taking into account computational constraints. If you have sufficient computational power and time, then try several coding matrices and choose the one with the best performance (e.g., check the confusion matrices for each model using `confusionmat`).
- Leave-one-out cross-validation (`Leaveout`) is inefficient for data sets with many observations. Instead, use k -fold cross-validation (`KFold`).

Algorithms

Custom Coding Design Matrices

Custom coding matrices must have a certain form. The software validates custom coding matrices by ensuring:

- Every element is -1, 0, or 1.
- Every column contains at least one -1 and one 1.
- For all distinct column vectors u and v , $u \neq v$ and $u \neq -v$.
- All rows vectors are unique.
- The matrix can separate any two classes. That is, you can travel from any row to any other row following these rules:
 - You can move vertically from 1 to -1 or -1 to 1.
 - You can move horizontally from a nonzero element to another nonzero element.
 - You can use a column of the matrix for a vertical move only once.

If it is not possible to move from row i to row j using these rules, then classes i and j cannot be separated by the design. For example, in the coding design

$$\begin{bmatrix} 1 & 0 \\ -1 & 0 \\ 0 & 1 \\ 0 & -1 \end{bmatrix}$$

classes 1 and 2 cannot be separated from classes 3 and 4 (that is, you cannot move horizontally from the -1 in row 2 to column 2 since there is a 0 in that position). Therefore, the software rejects this coding design.

Parallel Computing

If you use parallel computing (see `Options`), then `fitcecoc` trains binary learners in parallel.

Prior Probabilities and Cost

- Prior probabilities — The software normalizes the specified class prior probabilities (`Prior`) for each binary learner. Let M be the coding design matrix and $I(A,c)$ be an indicator matrix. The indicator matrix has the same dimensions as A . If the corresponding element of A is c , then the indicator matrix has elements equaling one, and zero otherwise. Let M_{+1} and M_{-1} be K -by- L matrices such that:
 - $M_{+1} = M \circ I(M,1)$, where \circ is element-wise multiplication (that is, `Mplus = M.*(M == 1)`). Also, let $m_l^{(+1)}$ be column vector l of M_{+1} .
 - $M_{-1} = -M \circ I(M,-1)$ (that is, `Mminus = -M.*(M == -1)`). Also, let $m_l^{(-1)}$ be column vector l of M_{-1} .

Let $\pi_l^{+1} = m_l^{(+1)} \circ \pi$ and $\pi_l^{-1} = m_l^{(-1)} \circ \pi$, where π is the vector of specified, class prior probabilities (`Prior`).

Then, the positive and negative, scalar class prior probabilities for binary learner l are

$$\hat{\pi}_l^{(j)} = \frac{\|\pi_l^{(j)}\|_1}{\|\pi_l^{(+1)}\|_1 + \|\pi_l^{(-1)}\|_1},$$

where $j = \{-1,1\}$ and $\|a\|_1$ is the one-norm of a .

- **Cost** — The software normalizes the K -by- K cost matrix C (**Cost**) for each binary learner. For binary learner l , the cost of classifying a negative-class observation into the positive class is

$$c_l^{-+} = \left(\pi_l^{(-1)} \right) C \pi_l^{(+1)}.$$

Similarly, the cost of classifying a positive-class observation into the negative class is

$$c_l^{+-} = \left(\pi_l^{(+1)} \right) C \pi_l^{(-1)}.$$

The cost matrix for binary learner l is

$$C_l = \begin{bmatrix} 0 & c_l^{-+} \\ c_l^{+-} & 0 \end{bmatrix}.$$

ECOC models accommodate misclassification costs by incorporating them with class prior probabilities. If you specify **Prior** and **Cost**, then the software adjusts the class prior probabilities as follows:

$$\bar{\pi}_l^{-1} = \frac{c_l^{-+} \hat{\pi}_l^{-1}}{c_l^{-+} \hat{\pi}_l^{-1} + c_l^{+-} \hat{\pi}_l^{+1}}$$

$$\bar{\pi}_l^{+1} = \frac{c_l^{+-} \hat{\pi}_l^{+1}}{c_l^{-+} \hat{\pi}_l^{-1} + c_l^{+-} \hat{\pi}_l^{+1}}.$$

Random Coding Design Matrices

For a given number of classes, for example, K , the software generates random coding design matrices as follows.

- 1 The software generates one of the following:

29-1910

- a **Dense random** — The software assigns a 1 or -1 with equal probability to each element of the K -by- L_d coding design matrix, where $L_d \approx \lceil 10 \log_2 K \rceil$.

- b** Sparse random — The software assigns a 1 to each element of the K -by- L_s coding design matrix with probability 0.25, a -1 with probability 0.25, and a 0 with probability 0.5, where $L_s \approx \lceil 15 \log_2 K \rceil$.
- 2** If a column does not contain at least one 1 and at least one -1, then the software removes that column.
- 3** For distinct columns u and v , if $u = v$ or $u = -v$, then the software removes v from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal pairwise row distance based on the Hamming measure ([4]) given by

$$\Delta(k_1, k_2) = 0.5 \sum_{l=1}^L |m_{k_1, l} - m_{k_2, l}|,$$

where $m_{k,l}$ is an element of coding design matrix j .

Support Vector Storage

For linear, SVM binary learners, and for efficiency, `fitcecoc` empties the properties `Alpha`, `SupportVectorLabels`, and `SupportVectors`. `fitcecoc` lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear, SVM template that specifies storing support vectors to `fitcecoc`. For example, enter:

```
t = templateSVM('SaveSupportVectors', 'on')
Mdl = fitcecoc(X, Y, 'Learners', t);
```

You can remove the support vectors and related values by passing the resulting `ClassificationECOC` model to `discardSupportVectors`.

fitcensemble

Fit ensemble of learners for classification

Syntax

```
Mdl = fitcensemble(Tbl,ResponseVarName)
```

```
Mdl = fitcensemble(Tbl,formula)
```

```
Mdl = fitcensemble(Tbl,Y)
```

```
Mdl = fitcensemble(X,Y)
```

```
Mdl = fitcensemble( ____,Name,Value)
```

Description

`Mdl = fitcensemble(Tbl,ResponseVarName)` returns the trained classification ensemble model object (`Mdl`) that contains the results of boosting 100 classification trees and the predictor and response data in the table `Tbl`. `ResponseVarName` is the name of the response variable in `Tbl`. By default, `fitcensemble` uses `LogitBoost` for binary classification and `AdaBoostM2` for multiclass classification.

`Mdl = fitcensemble(Tbl,formula)` applies `formula` to fit the model to the predictor and response data in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`. For example, `'Y~X1+X2+X3'` fits the response variable `Tbl.Y` as a function of the predictor variables `Tbl.X1`, `Tbl.X2`, and `Tbl.X3`.

`Mdl = fitcensemble(Tbl,Y)` treats all variables in the table `Tbl` as predictor variables. `Y` is the array of class labels that is not in `Tbl`.

`Mdl = fitcensemble(X,Y)` uses the predictor data in the matrix `X` and the array of class labels in `Y`.

`Mdl = fitcensemble(____,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments and any of the input arguments in the previous syntaxes. For example, you can specify the number of learning cycles, the ensemble-aggregation method, or to implement 10-fold cross-validation.

Examples

Train Classification Ensemble

Create a predictive classification ensemble using all available predictor variables in the data. Then, train another ensemble using fewer predictors. Compare the in-sample predictive accuracies of the ensembles.

Load the `census1994` data set.

```
load census1994
```

Train an ensemble of classification models using the entire data set and default options.

```
Mdl1 = fitcensemble(adultdata, 'salary')
```

```
Mdl1 =
```

```
classreg.learning.classif.ClassificationEnsemble
    PredictorNames: {1×14 cell}
    ResponseName: 'salary'
    CategoricalPredictors: [2 4 6 7 8 9 10 14]
    ClassNames: [<=50K >50K]
    ScoreTransform: 'none'
    NumObservations: 32561
    NumTrained: 100
    Method: 'LogitBoost'
    LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number o
    FitInfo: [100×1 double]
    FitInfoDescription: {2×1 cell}
```

`Mdl1` is a `ClassificationEnsemble` model. Some notable characteristics of `Mdl1` are:

- Because two classes are represented in the data, `LogitBoost` is the ensemble-aggregation algorithm.
- Because the ensemble-aggregation method is a boosting algorithm, classification trees that allow a maximum of 10 splits compose the ensemble.
- One hundred trees compose the ensemble.

Use the classification ensemble to predict the labels of a random set of five observations from the data. Compare the predicted labels with their true values.

```
rng(1) % For reproducibility
[pX,pIdx] = datasample(adultdata,5);
label = predict(Mdl1,pX);
table(label,adultdata.salary(pIdx),'VariableNames',{'Predicted','Truth'})
```

```
ans =
```

```
5×2 table
```

Predicted	Truth
<=50K	<=50K
<=50K	<=50K
<=50K	<=50K
<=50K	<=50K
<=50K	<=50K

Train a new ensemble using age and education only.

```
Mdl2 = fitcensemble(adultdata,'salary ~ age + education');
```

Compare the resubstitution losses between Mdl1 and Mdl2.

```
rsLoss1 = resubLoss(Mdl1)
rsLoss2 = resubLoss(Mdl2)
```

```
rsLoss1 =
```

```
0.1077
```

```
rsLoss2 =
```

```
0.2037
```

The in-sample misclassification rate for the ensemble that uses all predictors is lower.

Estimate Generalization Error of Boosting Ensemble

Estimate the generalization error of ensemble of boosted classification trees.

Load the `ionosphere` data set.

```
load ionosphere
```

Cross-validate an ensemble of classification trees using `AdaBoostM1` and 10-fold cross-validation. Specify that each tree should be split a maximum of five times using a decision tree template.

```
rng(5); % For reproducibility
t = templateTree('MaxNumSplits',5);
Mdl = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t,'CrossVal','on');
```

`Mdl` is a `ClassificationPartitionedEnsemble` model.

Plot the cumulative, 10-fold cross-validated, misclassification rate. Display the estimated generalization error of the ensemble.

```
kflc = kfoldLoss(Mdl,'Mode','cumulative');
figure;
plot(kflc);
ylabel('10-fold Misclassification rate');
xlabel('Learning cycle');

estGenError = kflc(end)
```

```
estGenError =
    0.0684
```

`kfoldLoss` returns the generalization error by default. However, plotting the cumulative loss allows you to monitor how the loss changes as weak learners accumulate in the ensemble.

The ensemble achieves a misclassification rate of around 0.06 after accumulating about 50 weak learners. Then, the misclassification rate increase slightly as more weak learners enter the ensemble.

If you are satisfied with the generalization error of the ensemble, then, to create a predictive model, train the ensemble again using all of the settings except cross-

validation. However, it is good practice to tune hyperparameters, such as the maximum number of decision splits per tree and the number of learning cycles.

Optimize Classification Ensemble

This example shows how to optimize hyperparameters automatically using `fitcensemble`. The example uses the `ionosphere` data.

Load the data.

```
load ionosphere
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
rng default
Mdl = fitcensemble(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
    'expected-improvement-plus'))
```

    FitInfo: [481×1 double]
    FitInfoDescription: {2×1 cell}
```

The optimization searched over the methods for binary classification, over `NumLearningCycles`, over the `LearnRate` for applicable methods, and over the tree learner `MinLeafSize`. The output is the ensemble classifier with the minimum estimated cross-validation loss.

Create Predictive Ensemble Using Cross-Validation

One way to create an ensemble of boosted classification trees that has satisfactory predictive performance is by tuning the decision tree-complexity level using cross-validation. While searching for an optimal complexity level, tune the learning rate to minimize the number of learning cycles.

Load the `ionosphere` data set.

```
load ionosphere
```

To search for the optimal tree-complexity level:

- 1 Cross-validate a set of ensembles. Exponentially increase the tree-complexity level for subsequent ensembles from decision stump (one split) to at most $n - 1$ splits. n is the sample size. Also, vary the learning rate for each ensemble between 0.1 to 1.
- 2 Estimate the cross-validated misclassification rate of each ensemble.
- 3 For tree-complexity level $j, j = 1 \dots J$, compare the cumulative, cross-validated misclassification rate of the ensembles by plotting them against number of learning cycles. Plot separate curves for each learning rate on the same figure.
- 4 Choose the curve that achieves the minimal misclassification rate, and note the corresponding learning cycle and learning rate.

Cross-validate a deep classification tree and a stump. These classification trees serve as benchmarks.

```
rng(1); % For reproducibility
MdlDeep = fitctree(X,Y,'CrossVal','on','MergeLeaves','off',...
    'MinParentSize',1);
MdlStump = fitctree(X,Y,'MaxNumSplits',1,'CrossVal','on');
```

Cross-validate an ensemble of 150 boosted classification trees using 5-fold cross-validation. Using a tree template, vary the maximum number of splits using the values in the sequence $\{3^0, 3^1, \dots, 3^m\}$. m is such that 2^m is no greater than $n - 1$. For each variant, adjust the learning rate using each value in the set $\{0.1, 0.25, 0.5, 1\}$;

```
n = size(X,1);
m = floor(log(n - 1)/log(3));
learnRate = [0.1 0.25 0.5 1];
numLR = numel(learnRate);
maxNumSplits = 3.^(0:m);
numMNS = numel(maxNumSplits);
numTrees = 150;
Mdl = cell(numMNS,numLR);

for k = 1:numLR;
    for j = 1:numMNS;
        t = templateTree('MaxNumSplits',maxNumSplits(j));
        Mdl{j,k} = fitcensemble(X,Y,'NumLearningCycles',numTrees,...
            'Learners',t,'KFold',5,'LearnRate',learnRate(k));
    end
end
```

```

    end;
end;

```

Estimate the cumulative, cross-validated misclassification rate for each ensemble and the classification trees serving as benchmarks.

```

kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(learnRate)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);

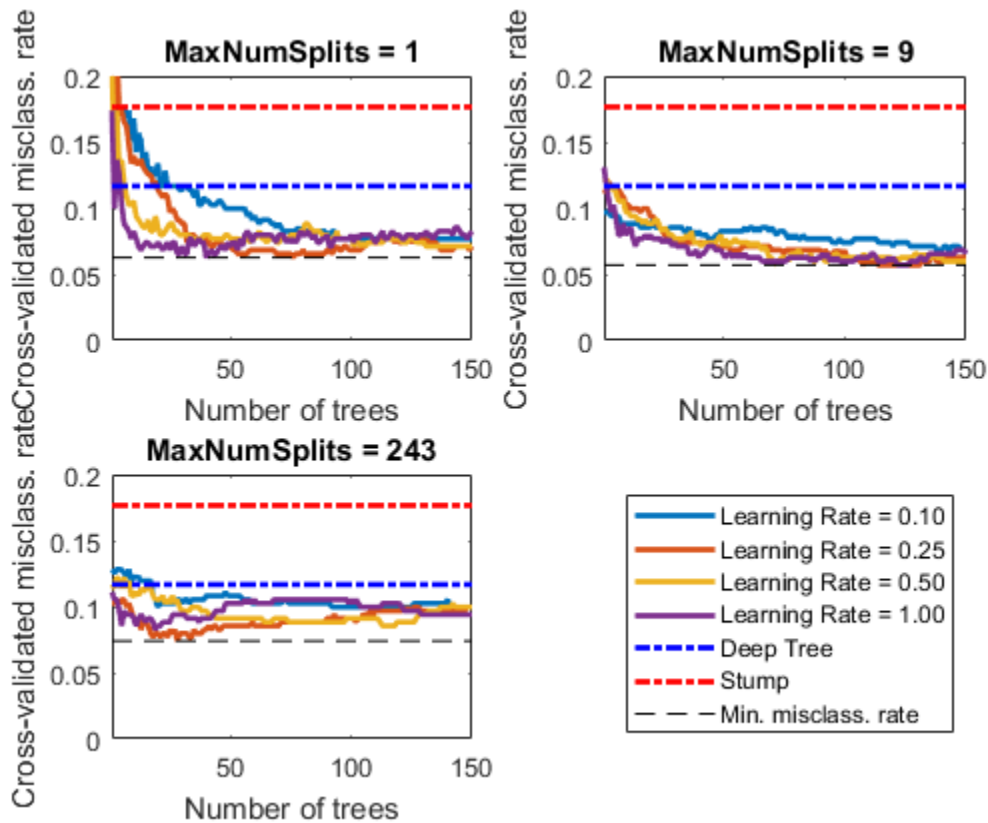

```

Plot how the cross-validated misclassification rate behaves as the number of trees in the ensemble increases. Plot the curves with respect to learning rate on the same plot, and plot separate plots for varying tree-complexity levels. Choose a subset of tree complexity levels to plot.

```

mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3;
    subplot(2,2,k);
    plot(squeeze(error(:,mnsPlot(k),:)), 'LineWidth',2);
    axis tight;
    hold on;
    h = gca;
    plot(h.XLim,[errorDeep errorDeep], '-.b', 'LineWidth',2);
    plot(h.XLim,[errorStump errorStump], '-.r', 'LineWidth',2);
    plot(h.XLim,min(min(error(:,mnsPlot(k),:)))*[1 1], '--k');
    h.YLim = [0 0.2];
    xlabel 'Number of trees';
    ylabel 'Cross-validated misclass. rate';
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))));
    hold off;
end;
hL = legend([cellstr(num2str(learnRate),'Learning Rate = %0.2f');...
            'Deep Tree';'Stump';'Min. misclass. rate']);
hL.Position(1) = 0.6;

```

Each curve contains a minimum cross-validated misclassification rate occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest misclassification rate overall.

```
[minErr,minErrIdxLin] = min(error(:));
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);

fprintf('\nMin. misclass. rate = %0.5f',minErr)
fprintf('\nOptimal Parameter Values:\nNum. Trees = %d',idxNumTrees);
fprintf('\nMaxNumSplits = %d\nLearning Rate = %0.2f\n',...
        maxNumSplits(idxMNS),learnRate(idxLR))
```

```

Min. misclass. rate = 0.05413
Optimal Parameter Values:
Num. Trees = 47
MaxNumSplits = 3
Learning Rate = 0.25

```

Create a predictive ensemble based on the optimal hyperparameters and the entire training set.

```

tFinal = templateTree('MaxNumSplits',maxNumSplits(idxMNS));
MdlFinal = fitcensemble(X,Y,'NumLearningCycles',idxNumTrees,...
    'Learners',tFinal,'LearnRate',learnRate(idxLR))

```

```
MdlFinal =
```

```

classreg.learning.classif.ClassificationEnsemble
    ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: {'b' 'g'}
        ScoreTransform: 'none'
    NumObservations: 351
    NumTrained: 47
        Method: 'LogitBoost'
        LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of
    FitInfo: [47×1 double]
    FitInfoDescription: {2×1 cell}

```

`MdlFinal` is a `ClassificationEnsemble`. To predict the whether a radar return is good given predictor data, pass the predictor data and `MdlFinal` to `predict`.

- “Supervised Learning Workflow and Algorithms” on page 18-2
- “Ensemble Methods” on page 18-71

Input Arguments

Tb1 — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. `Tbl` can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using `formula`.
- If `Tbl` does not contain the response variable, then specify the response data using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

Note: To save memory and execution time, supply `X` and `Y` instead of `Tbl`.

Data Types: `table`

ResponseVarName — Response variable name

name of response variable in `Tbl`

Response variable name, specified as the name of the response variable in `Tbl`.

You must specify `ResponseVarName` as a character vector. For example, if `Tbl.Y` is the response variable, then specify `ResponseVarName` as `'Y'`. Otherwise, `fitcensemble` treats all columns of `Tbl` as predictor variables.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

For classification, you can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitcensemble` determines the class order, and stores it in the `Mdl.ClassNames`.

Data Types: `char`

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response

variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char`

X — Predictor data

numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `double` | `single`

Y — Response data

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Response data, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Each entry in `Y` is the response to or label for the observation in the corresponding row of `X` or `Tbl`. The length of `Y` and the number of rows of `X` or `Tbl` must be equal. If the response variable is a character array, then each element must correspond to one row of the array.

You can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitcensemble` determines the class order, and stores it in the `Mdl.ClassNames`.

Data Types: `char` | `cell` | `categorical` | `logical` | `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

Note: You cannot use any cross-validation name-value pair along with `OptimizeHyperparameters`. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair.

Example: `'CrossVal','on','LearningRate',0.05` specifies to implement 10-fold cross-validation and to use 0.05 as the learning rate.

General Ensemble Options

'Method' — Ensemble-aggregation method

'AdaBoostM1' | 'LogitBoost' | 'GentleBoost' | 'RobustBoost' | 'LPBoost' | 'TotalBoost' | 'RUSBoost' | 'Subspace' | 'Bag' | 'AdaBoostM2' | ...

Ensemble-aggregation method, specified as the comma separated pair consisting of 'Method' and a character vector such as 'RUSBoost'.

Value	Description	Classification Problem Support	Additional Requirements
'AdaBoostM1'	Adaptive boosting	Binary only	-
'AdaBoostM2'	Adaptive boosting	Multiclass only	-
'Bag'	Bootstrap aggregating (e.g., random forest)	Binary and multiclass	-
'GentleBoost'	Gentle adaptive boosting	Binary only	-
'LogitBoost'	Adaptive logistic regression	Binary only	-
'LPBoost'	Linear programming boosting	Binary and multiclass	Optimization Toolbox license
'RobustBoost'	Robust boosting	Binary only	Optimization Toolbox license

Value	Description	Classification Problem Support	Additional Requirements
'RUSBoost'	Random undersampling boosting	Binary and multiclass	-
'Subspace'	Random subspace	Binary and multiclass	-
'TotalBoost'	Totally corrective boosting	Binary and multiclass	Optimization Toolbox license

For binary classification problems, the default is 'LogitBoost'. Otherwise, the default is 'AdaBoostM2'.

Example: 'Method', 'Bag'

Data Types: char

'NumLearningCycles' — Number of ensemble learning cycles

100 (default) | positive integer | 'AllPredictorCombinations'

Number of ensemble learning cycles, specified as a positive integer or 'AllPredictorCombinations'.

- If you specify a positive integer, then, at every learning cycle, the software trains one weak learner for every template object in `Learners`. Consequently, the software trains `NumLearningCycles* numel(Learners)` learners.
- If you specify 'AllPredictorCombinations', then set `Method` to 'Subspace' and specify one learner only for `Learners`. With these settings, the software trains learners for all possible combinations of predictors taken `NPredToSample` at a time. Consequently, the software trains `nchoosek(size(X,2), NPredToSample)` learners.

The software composes the ensemble using all trained learners and stores them in `Mdl.Trained`.

For more details, see “Tips” on page 29-1948.

Example: 'NumLearningCycles', 500

Data Types: single | double | char

'Learners' — Weak learners to use in ensemble

weak-learner name | weak-learner template object | cell vector of weak-learner template objects

Weak learners to use in the ensemble, specified as a weak-learner name, weak-learner template object, or cell array of weak-learner template objects.

Weak Learner	Weak-Learner Name	Template Object Creation Function	Method Settings
Discriminant analysis	'discriminant'	templateDiscrimin	Recommended for 'Subspace'
k nearest neighbors	'knn'	templateKNN	For 'Subspace' only
Decision tree	'tree'	templateTree	All methods except 'Subspace'

The defaults are:

- 'knn' if Method is 'Subspace'
- 'tree' if Method is 'Bag'
- `templateTree('MaxNumSplits',10)` if Method is any boosting method

If you specify 'Learners', learners explicitly, where learners is a weak-learner name or template object, then `fitcensemble` defers to the corresponding template object to choose any required default values for weak-learner name-value pair arguments. For example, if you specify 'Learners', 'tree' and a boosting algorithm, then the tree template object overrides the default maximum number of splits of ten, and grows decision stumps (one allowable split) instead.

For details on the number of learners to train, see `NumLearningCycles` and “Tips” on page 29-1948.

Example: For an ensemble composed of two types of classification trees, supply {t1 t2}, where t1 and t2 are classification tree templates.

'NPrint' — Printout frequency

'off' (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of 'NPrint' and a positive integer or 'off'.

To track the number of *weak learners* or *folds* that `fitcensemble` trained so far, specify a positive integer. That is, if you specify the positive integer m :

- Without also specifying any cross-validation option (for example, `CrossVal`), then `fitcensemble` displays a message to the command line every time it completes training m weak learners.
- And a cross-validation option, then `fitcensemble` displays a message to the command line every time it finishes training m folds.

If you specify `'off'`, then `fitcensemble` does not display a message when it completes training weak learners.

Tip: When training an ensemble of many weak learners on a large data set, specify a positive integer for `NPrint`.

Example: `'NPrint',5`

Data Types: `single | double | char`

'CategoricalPredictors' — Categorical predictors list

character matrix | logical vector | numeric vector | cell array of character vectors | `'all'`

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following:

- A numeric vector with indices from 1 through p , where p is the number of columns of X .
- A logical vector of length p , where a `true` entry means that the corresponding column of X is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
- `'all'`, meaning all predictors are categorical.

Specification of `CategoricalPredictors` is appropriate if:

- 'tree'
- 'knn', when all predictors are categorical

By default, if the predictor data is in a matrix (*X*), `fitcensemble` assumes that none of the predictors are categorical. If the predictor data is in a table (*Tbl*), `fitcensemble` assumes that a variable is categorical if it contains logical values, categorical values, or a cell array of character vectors.

Example: 'CategoricalPredictors', 'all'

Data Types: single | double | char

'PredictorNames' — Predictor variable names

cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply *X* and *Y*, then you can use 'PredictorNames' to give the predictor variables in *X* names.
 - The order of the names in `PredictorNames` must correspond to the column order of *X*. That is, `PredictorNames{1}` is the name of $X(:, 1)$, `PredictorNames{2}` is the name of $X(:, 2)$, and so on. Also, `size(X, 2)` and `numel(PredictorNames)` must be equal.
 - By default, `PredictorNames` is `{x1, x2, ...}`.
- If you supply *Tbl*, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, `fitcensemble` uses the predictor variables in `PredictorNames` and the response only in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It good practice to specify the predictors for training using one of 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength', 'SepalWidth', 'PedalLength', 'PedalWidth'}

Data Types: cell

'ResponseName' — Response variable name`'Y'` (default) | character vector

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName', 'response'`

Data Types: char

Cross-Validation Options**'CrossVal' — Cross-validation flag**`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval` or `crossval`.

Example: `'Crossval', 'on'`

Data Types: char

'CVPartition' — Cross-validation partition`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', p`, then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify, e.g., `'KFold', k`, then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold', 5`

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations, where n is `size(Mdl.X,1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Leaveout', 'on'

Data Types: char

Other Classification Options

'ClassNames' — Names of classes to use for training

categorical array | cell array of character vectors | character array | logical vector | numeric vector

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` must be the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a', 'b', 'c'}`. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames', `{'a', 'c'}`.

The default is the set of all distinct class names in `Y`.

Example: `'ClassNames', {'b', 'g'}`

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

'Cost' — Misclassification cost

`square matrix` | `structure array`

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure. If you specify:

- The square matrix `Cost`, then `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, also specify the `ClassNames` name-value pair argument.
- The structure `S`, then it must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
 - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

The default is `ones(K) - eye(K)`, where `K` is the number of distinct classes.

Note: `fitcensemble` uses `Cost` to adjust the prior class probabilities specified in `Prior`. Then, `fitcensemble` uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: `'Cost', [0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double` | `single` | `struct`

'Prior' — Prior probabilities

`'empirical'` (default) | `'uniform'` | `numeric vector` | `structure array`

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
<code>'empirical'</code>	The class prior probabilities are the class relative frequencies in <code>Y</code> .

Value	Description
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>SVModel.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure array	A structure <code>S</code> with two fields: <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

`fitcensemble` normalizes the prior probabilities in `Prior` to sum to 1.

Example: `struct('ClassNames',
{'setosa','versicolor','virginica'}), 'ClassProbs', 1:3)`

Data Types: char | double | single | struct

'Weights' — Observation weights

numeric vector of positive values | character vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n, 1)`, where n is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char`

Sampling Options for Boosting Methods and Bagging

'FResample' — Fraction of training set to resample

1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of 'FResample' and a positive scalar in (0,1].

To use 'FResample', specify 'bag' for `Method` or set `Resample` to 'on'.

Example: 'FResample',0.75

Data Types: `single` | `double`

'Replace' — Flag indicating to sample with replacement

'on' (default) | 'off'

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of 'Replace' and 'off' or 'on'.

- For 'on', the software samples the training observations with replacement.
- For 'off', the software samples the training observations without replacement. If you set `Resample` to 'on', then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set `Method` to 'bag' or set `Resample` to 'on', `Replace` has no effect.

Example: 'Replace','off'

Data Types: `char`

'Resample' — Flag indicating to resample

'off' | 'on'

Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If `Method` is any boosting method, then:
 - `'Resample', 'on'` specifies to sample training observations using updated weights as the multinomial sampling probabilities.
 - `'Resample', 'off'` specifies to reweight observations at every learning iteration. This setting is the default.
- If `Method` is `'bag'`, then `'Resample'` must be `'on'`. The software resamples a fraction of the training observations (see `FResample`) with or without replacement (see `Replace`).

AdaBoostM1, AdaBoostM2, LogitBoost, and GentleBoost Method Options

'LearnRate' — Learning rate for shrinkage

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, `0.1` is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: `'LearnRate', 0.1`

Data Types: `single` | `double`

RUSBoost Method Options

'LearnRate' — Learning rate for shrinkage

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, `0.1` is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: `'LearnRate', 0.1`

Data Types: `single` | `double`

'RatioToSmallest' — Sampling proportion with respect to lowest-represented class

positive numeric scalar | numeric vector of positive values

Sampling proportion with respect to the lowest-represented class, specified as the comma-separated pair consisting of `'RatioToSmallest'` and a numeric scalar or numeric vector of positive values with length equal to the number of distinct classes in the training data.

Suppose that there are K classes in the training data and the lowest-represented class has m observations in the training data.

- If you specify the positive numeric scalar s , then `fitcensemble` samples $s*m$ observations from each class, that is, it uses the same sampling proportion for each class. For more details, see “Algorithms” on page 29-2434.
- If you specify the numeric vector $[s_1, s_2, \dots, s_K]$, then `fitcensemble` samples s_i*m observations from class i , $i = 1, \dots, K$. The elements of `RatioToSmallest` correspond to the order of the class names specified using `ClassNames` (see “Tips” on page 29-2432).

The default value is `ones(K, 1)`, which specifies to sample m observations from each class.

Example: `'RatioToSmallest', [2, 1]`

Data Types: `single` | `double`

LPBoost and TotalBoost Method Options

'MarginPrecision' — Margin precision to control convergence speed

0.1 (default) | numeric scalar in [0,1]

Margin precision to control convergence speed, specified as the comma-separated pair consisting of `'MarginPrecision'` and a numeric scalar in the interval [0,1]. `MarginPrecision` affects the number of boosting iterations required for convergence.

Tip: To train an ensemble using many learners, specify a small value for `MarginPrecision`. For training using a few learners, specify a large value.

Example: `'MarginPrecision', 0.5`

Data Types: `single` | `double`

RobustBoost Method Options

'RobustErrorGoal' — Target classification error

0.1 (default) | nonnegative numeric scalar

Target classification error, specified as the comma-separated pair consisting of 'RobustErrorGoal' and a nonnegative numeric scalar. The upper bound on possible values depends on the values of RobustMarginSigma and RobustMaxMargin. However, the upper bound cannot exceed 1.

Tip: For a particular training set, usually there is an optimal range for RobustErrorGoal. If you set it too low or too high, then the software can produce a model with poor classification accuracy. Try cross-validating to search for the appropriate value.

Example: `'RobustErrorGoal',0.05`

Data Types: `single` | `double`

'RobustMarginSigma' — Classification margin distribution spread

0.1 (default) | positive numeric scalar

Classification margin distribution spread over the training data, specified as the comma-separated pair consisting of 'RobustMarginSigma' and a positive numeric scalar. Before specifying RobustMarginSigma, consult the literature on RobustBoost, for example, [19].

Example: `'RobustMarginSigma',0.5`

Data Types: `single` | `double`

'RobustMaxMargin' — Maximal classification margin

0 (default) | nonnegative numeric scalar

Maximal classification margin in the training data, specified as the comma-separated pair consisting of 'RobustMaxMargin' and a nonnegative numeric scalar. The software minimizes the number of observations in the training data having classification margins below RobustMaxMargin.

Example: `'RobustMaxMargin',1`

Data Types: `single` | `double`

Random Subspace Method Options

'`NPredToSample`' — Number of predictors to sample

1 (default) | positive integer

Number of predictors to sample for each random subspace learner, specified as the comma-separated pair consisting of '`NPredToSample`' and a positive integer in the interval $1, \dots, p$, where p is the number of predictor variables (`size(X,2)` or `size(Tbl,2)`).

Data Types: `single` | `double`

Hyperparameter Optimization

'`OptimizeHyperparameters`' — Parameters to optimize

'`none`' (default) | '`auto`' | '`all`' | cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as:

- '`none`' — Do not optimize.
- '`auto`' — Use `{'Method', 'NumLearningCycles', 'LearnRate'}` along with the default parameters for the specified Learners:
 - `Learners = 'tree'` (default) — `{'MinLeafSize'}`
 - `Learners = 'discriminant'` — `{'Delta', 'Gamma'}`
 - `Learners = 'knn'` — `{'Distance', 'NumNeighbors'}`

Note: For hyperparameter optimization, `Learners` must be a single argument, not a cell array.

- '`all`' — Optimize all eligible parameters.
- Cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitcensemble` by varying the parameters. For information about cross-validation

loss (albeit in a different context), see “Classification Loss” on page 29-3219. To control the cross-validation type and other aspects of the optimization, use the `OptimizeHyperparameterOptimizationOptions` name-value pair.

Note: `OptimizeHyperparameters` values override any values you set using other name-value pairs. For example, setting `OptimizeHyperparameters` to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitcensemble` are:

- **Method** — Depends on the number of classes.
 - Two classes — Eligible methods are 'Bag', 'GentleBoost', 'LogitBoost', 'AdaBoostM1', and 'RUSBoost'.
 - Three or more classes — Eligible methods are 'Bag', 'AdaBoostM2', and 'RUSBoost'.
- **NumLearningCycles** — `fitcensemble` searches among positive integers, by default log-scaled with range [10,500].
- **LearnRate** — `fitcensemble` searches among positive reals, by default log-scaled with range [1e-3,1].
- The eligible hyperparameters for the chosen Learners:

Learners	Eligible Hyperparameters Bold = Used By Default	Default Range
'discriminant'	Delta	Log-scaled in the range [1e-6,1e3]
	DiscrimType	'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', and 'pseudoQuadratic'
	Gamma	Real values in [0,1]
'knn'	Distance	'cityblock', 'chebychev', 'correlation', 'cosine', 'euclidean', 'hamming', 'jaccard', 'mahalanobis', 'minkowski', 'seuclidean', and 'spearman'

Learners	Eligible Hyperparameters Bold = Used By Default	Default Range
	DistanceWeight	'equal', 'inverse', and 'squaredinverse'
	Exponent	Positive values in [0.5,3]
	NumNeighbors	Positive integer values log-scaled in the range [1, max(2, round(NumObservations/2))]
	Standardize	'true' and 'false'
'tree'	MaxNumSplits	Integers log-scaled in the range [1, max(2, NumObservations-1)]
	MinLeafSize	Integers log-scaled in the range [1, max(2, floor(NumObservations/2))]
	NumVariablesToSample	Integers in the range [1, max(2, NumPredictors)]
	SplitCriterion	'gdi', 'deviance', and 'twoing'

Alternatively, use `hyperparameters` with your chosen Learners.

```
load fisheriris % hyperparameters requires data and learner
params = hyperparameters('fitcensemble', meas, species, 'Tree');
```

To see the eligible and default hyperparameters, examine `params`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcensemble', meas, species, 'Tree');
params(4).Range = [1,30];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression, and the misclassification rate for classification. To control the iterative display, set the `HyperparameterOptimizationOptions` name-value pair, `Verbose` field. To

control the plots, set the `HyperparameterOptimizationOptions` name-value pair, `ShowPlots` field.

For an example, see “Optimize Classification Ensemble” on page 29-1918.

Example: 'auto'

Data Types: char | cell

'HyperparameterOptimizationOptions' — Options for optimization structure

Options for optimization, specified as a structure. Modifies the effect of the `OptimizeHyperparameters` name-value pair. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the <code>commandsortrows(Mdl.ParameterOptim</code></p>	'bayesopt'
AcquisitionFunc	<ul style="list-style-type: none"> 'expected-improvement-per-second-plus' 'expected-improvement' 'expected-improvement-plus' 'expected-improvement-per-second' 'lower-confidence-bound' 	'expected-improvement-per-second-plus'

Field Name	Values	Default
	<ul style="list-style-type: none"> 'probability-of-improvement' <p>For details, see the <code>bayesopt</code> <code>AcquisitionFunctionName</code> name-value pair, or “Acquisition Function Types” on page 10-4.</p>	
<code>MaxObjectiveEvaluations</code>	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
<code>NumGridDivisions</code>	For 'gridsearch', the number of values in each dimension. Can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. Ignored for categorical variables.	10
<code>ShowPlots</code>	Logical value indicating whether to show plots. If <code>true</code> , plots the best objective function value against iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is 'bayesopt', then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
<code>SaveIntermediateResults</code>	Logical value indicating whether to save results when <code>Optimizer</code> is 'bayesopt'. If <code>true</code> , overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>

Field Name	Values	Default
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesoptVerbose</code> name-value pair.	1
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code>	Kfold = 5
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example: `struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

Mdl1 — Trained classification ensemble model

ClassificationBaggedEnsemble model object | ClassificationEnsemble model object | ClassificationPartitionedEnsemble cross-validated model object

Trained ensemble model, returned as one of the model objects in this table.

Model Object	Specify Any Cross-Validation Options?	Method Setting	Resample Setting
ClassificationBaggedEns	No	'Bag'	'on'
ClassificationEnsemble	No	Any ensemble-aggregation method for classification	'off'
ClassificationPartitioned	Yes	Any classification ensemble-aggregation method	'off' or 'on'

The name-value pair arguments that control cross-validation are `CrossVal`, `Holdout`, `KFold`, `Leaveout`, and `CVPartition`.

To reference properties of `Mdl`, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

Tips

- `NumLearningCycles` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume` for classification problems.
- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.
- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.
- If the ensemble-aggregation method (`Method`) is 'bag' and:

- The misclassification cost (**Cost**) is highly imbalanced, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty.
- The class prior probabilities (**Prior**) are highly skewed, the software oversamples unique observations from the class that has a large prior probability.

For smaller sample sizes, these combinations can result in a low relative frequency of out-of-bag observations from the class that has a large penalty or prior probability. Consequently, the estimated out-of-bag error is highly variable and it can be difficult to interpret. To avoid large estimated out-of-bag error variances, particularly for small sample sizes, set a more balanced misclassification cost matrix using **Cost** or a less skewed prior probability vector using **Prior**.

- Because the order of some input and output arguments correspond to the distinct classes in the training data, it is good practice to specify the class order using the **ClassNames** name-value pair argument.
 - To determine the class order quickly, remove all observations from the training data that are unclassified (that is, have a missing label), obtain and display an array of all the distinct classes, and then specify the array for **ClassNames**. For example, suppose the response variable (**Y**) is a cell array of labels. This code specifies the class order in the variable **classNames**.

```
Ycat = categorical(Y);
classNames = categories(Ycat)
categorical assigns <undefined> to unclassified observations and
categories excludes <undefined> from its output. Therefore, if you use this
code for cell arrays of labels or similar code for categorical arrays, then you do not
have to remove observations with missing labels to obtain a list of the distinct
classes.
```

- To specify that the class order from lowest-represented label to most-represented, then quickly determine the class order (as in the previous bullet), but arrange the classes in the list by frequency before passing the list to **ClassNames**. Following from the previous example, this code specifies the class order from lowest- to most-represented in **classNamesLH**.

```
Ycat = categorical(Y);
classNames = categories(Ycat);
freq = countcats(Ycat);
[~,idx] = sort(freq);
classNamesLH = classNames(idx);
```

Algorithms

- For details of ensemble-aggregation algorithms, see “Ensemble Algorithms” on page 18-169.
- If you specify `Method` to be a boosting algorithm and `Learners` to be decision trees, then the software grows shallow decision trees by default. You can adjust tree depth by specifying the `MaxNumSplits`, `MinLeafSize`, and `MinParentSize` name-value pair arguments using `templateTree`.
- `fitcensemble` generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class can be low. Therefore, the estimated out-of-bag error can have a large variance and can be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.
- For the RUSBoost ensemble-aggregation method (`Method`), the name-value pair argument `RatioToSmallest` specifies the sampling proportion for each class with respect to the lowest-represented class. For example, suppose that there are two classes in the training data: *A* and *B*. *A* have 100 observations and *B* have 10 observations. and that the lowest-represented class has *m* observations in the training data.
 - If you set `'RatioToSmallest', 2`, then $s*m = 2*10 = 20$. Consequently, `fitcensemble` trains every learner using 20 observations from class *A* and 20 observations from class *B*. If you set `'RatioToSmallest', [2 2]`, then you obtain the same result.
 - If you set `'RatioToSmallest', [2, 1]`, then $s1*m = 2*10 = 20$ and $s2*m = 1*10 = 10$. Consequently, `fitcensemble` trains every learner using 20 observations from class *A* and 10 observations from class *B*.
- For dual-core systems and above, `fitcensemble` parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

fitcknn

Fit k -nearest neighbor classifier

Syntax

```
Mdl = fitcknn(Tbl,ResponseVarName)
```

```
Mdl = fitcknn(Tbl,formula)
```

```
Mdl = fitcknn(Tbl,Y)
```

```
Mdl = fitcknn(X,Y)
```

```
Mdl = fitcknn( ____,Name,Value)
```

Description

`Mdl = fitcknn(Tbl,ResponseVarName)` returns a k -nearest neighbor classification model based on the input variables (also known as predictors, features, or attributes) in the table `Tbl` and output (response) `Tbl.ResponseVarName`.

`Mdl = fitcknn(Tbl,formula)` returns a k -nearest neighbor classification model based on the input variables in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl`.

`Mdl = fitcknn(Tbl,Y)` returns a k -nearest neighbor classification model based on the predictor variables in the table `Tbl` and response array `Y`.

`Mdl = fitcknn(X,Y)` returns a k -nearest neighbor classification model based on the predictor data `X` and response `Y`.

`Mdl = fitcknn(____,Name,Value)` fits a model with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the tie-breaking algorithm, distance metric, or observation weights.

Examples

Train a k -Nearest Neighbor Classifier

Construct a k -nearest neighbor classifier for Fisher's iris data, where k , the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

```
load fisheriris
X = meas;
Y = species;
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a 5-nearest neighbors classifier. It is good practice to standardize noncategorical predictor data.

```
Mdl = fitcknn(X,Y, 'NumNeighbors',5, 'Standardize',1)
```

```
Mdl =
```

```
ClassificationKNN
    ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    NumObservations: 150
        Distance: 'euclidean'
    NumNeighbors: 5
```

Mdl is a trained `ClassificationKNN` classifier, and some of its properties display in the Command Window.

To access the properties of Mdl, use dot notation.

```
Mdl.ClassNames
Mdl.Prior
```

```
ans =
```

```

3×1 cell array

    'setosa'
    'versicolor'
    'virginica'

ans =

    0.3333    0.3333    0.3333

```

`Mdl.Prior` contains the class prior probabilities, which are settable using the name-value pair argument `'Prior'` in `fitcknn`. The order of the class prior probabilities corresponds to the order of the classes in `Mdl.ClassNames`. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3 respectively.

```
Mdl.Prior = [0.5 0.2 0.3];
```

You can pass `Mdl` to, for example, `predict(ClassificationKNN)` to label new measurements, or `crossval(ClassificationKNN)` to cross validate the classifier.

Train a *k*-Nearest Neighbor Classifier Using the Minkowski Metric

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of character vectors that contains the corresponding iris species.

Train a 3-nearest neighbors classifier using the Minkowski metric. To use the Minkowski metric, you must use an exhaustive searcher. It is good practice to standardize noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',3,...
    'NSMethod','exhaustive','Distance','minkowski',...
    'Standardize',1);
```

Mdl is a ClassificationKNN classifier.

You can examine the properties of Mdl by double-clicking Mdl in the Workspace window. This opens the Variable Editor.

Name	Value	Min	Max
Mdl	1x1 ClassificationKNN		
meas	150x4 double	0.1000	7.9
species	150x1 cell		
X	150x4 double	0.1000	7.9
Y	150x1 cell		

Property	Value	Min	Max
NumNeighbors	3	3	3
Distance	'minkowski'		
DistParameter	2	2	2
IncludeTies	0		
DistanceWeight	'equal'		
BreakTies	'smallest'		
NSMethod	'exhaustive'		

Train a k -Nearest Neighbor Classifier Using a Custom Distance Metric

Train a k -nearest neighbor classifier using the chi-square distance.

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

The chi-square distance between j -dimensional points x and z is

$$\chi(x, z) = \sqrt{\sum_{j=1}^J w_j (x_j - z_j)^2},$$

where w_j is a weight associated with dimension j .

Specify the chi-square distance function. The distance function must:

- Take one row of X , e.g., x , and the matrix Z .
- Compare x to each row of Z .
- Return a vector D of length n_z , where n_z is the number of rows of Z . Each element of D is the distance between the observation corresponding to x and the observations corresponding to each row of Z .

```
chiSqrDist = @(x,Z,wt) sqrt((bsxfun(@minus,x,Z).^2)*wt);
```

This example uses arbitrary weights for illustration.

Train a 3-nearest neighbor classifier. It is good practice to standardize noncategorical predictor data.

```
k = 3;
w = [0.3; 0.3; 0.2; 0.2];
KNNMdl = fitcknn(X,Y,'Distance',@(x,Z)chiSqrDist(x,Z,w),...
    'NumNeighbors',k,'Standardize',1);
```

KNNMdl is a ClassificationKNN class classifier.

Cross validate the KNN classifier using the default 10-fold cross validation. Examine the classification error.

```
rng(1); % For reproducibility
CVKNNMdl = crossval(KNNMdl);
classError = kfoldLoss(CVKNNMdl)
```

```
classError =  
    0.0600
```

CVKNNMd1 is a ClassificationPartitionedModel class classifier. The 10-fold classification error is 4%.

Compare the classifier with one that uses a different weighting scheme.

```
w2 = [0.2; 0.2; 0.3; 0.3];  
CVKNNMd12 = fitcknn(X,Y,'Distance',@(x,Z)chiSqrDist(x,Z,w2),...  
    'NumNeighbors',k,'KFold',10,'Standardize',1);  
classError2 = kfoldLoss(CVKNNMd12)
```

```
classError2 =  
    0.0400
```

The second weighting scheme yields a classifier that has better out-of-sample performance.

Optimize Fitted KNN Classifier

This example shows how to optimize hyperparameters automatically using `fitcknn`. The example uses the Fisher iris data.

Load the data.

```
load fisheriris  
X = meas;  
Y = species;
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng(1)  
Md1 = fitcknn(X,Y,'OptimizeHyperparameters','auto',...  
    'HyperparameterOptimizationOptions',...)
```

```
struct('AcquisitionFunctionName','expected-improvement-plus')
```

- “Modify KNN Classifier” on page 18-33

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of **Tbl** corresponds to one observation, and each column corresponds to one predictor variable. Optionally, **Tbl** can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If **Tbl** contains the response variable, and you want to use all remaining variables in **Tbl** as predictors, then specify the response variable using **ResponseVarName**.

If **Tbl** contains the response variable, and you want to use only a subset of the remaining variables in **Tbl** as predictors, then specify a formula using **formula**.

If **Tbl** does not contain the response variable, then specify a response variable using **Y**. The length of response variable and the number of rows of **Tbl** must be equal.

Data Types: table

ResponseVarName — Response variable name

name of variable in **Tbl**

Response variable name, specified as the name of a variable in **Tbl**.

You must specify **ResponseVarName** as a character vector. For example, if the response variable **Y** is stored as **Tbl.Y**, then specify it as **'Y'**. Otherwise, the software treats all columns of **Tbl**, including **Y**, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If **Y** is a character array, then each element must correspond to one row of the array.

It is good practice to specify the order of the classes using the **ClassNames** name-value pair argument.

Data Types: char

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of **'Y~X1+X2+X3'**. In this form, **Y** represents the response

variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char`

Y — Class labels

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X`.

The software considers `NaN`, `' '` (empty character vector), and `<undefined>` values in `Y` to be missing values. Consequently, the software does not train using observations with a missing response.

Data Types: `single` | `double` | `logical` | `char` | `cell`

X — Predictor data

numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation (also known as an instance or example), and each column corresponds to one predictor variable (also known as a feature).

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Note: You cannot use any cross-validation name-value pair along with `OptimizeHyperparameters`. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair.

Example:

```
'NumNeighbors',3,'NSMethod','exhaustive','Distance','minkowski'
```

specifies a classifier for three-nearest neighbors using the nearest neighbor search method and the Minkowski metric.

Model Parameters

'BreakTies' — Tie-breaking algorithm

'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the `K` nearest neighbors.

Example: `'BreakTies','nearest'`

'BucketSize' — Maximum data points in node

50 (default) | positive integer value

Maximum number of data points in the leaf node of the *kd*-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer value. This argument is meaningful only when `NSMethod` is `'kdtree'`.

Example: `'BucketSize',40`

Data Types: `single` | `double`

'CategoricalPredictors' — Categorical predictor flag

`[]` (default) | `'all'`

Categorical predictor flag, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following:

- `'all'` — All predictors are categorical.
- `[]` — No predictors are categorical.

When you set `CategoricalPredictors` to `'all'`, the default `Distance` is `'hamming'`.

Example: `'CategoricalPredictors','all'`

'ClassNames' — Names of classes to use for training

categorical array | cell array of character vectors | character array | logical vector | numeric vector

Names of classes to use for training, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` must be the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default is the set of all distinct class names in `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where $\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of **Cost**, additionally specify the **ClassNames** name-value pair argument.
- Structure **S** having two fields: **S.ClassNames** containing the group names as a variable of the same type as **Y**, and **S.ClassificationCosts** containing the cost matrix.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Data Types: single | double | struct

'Cov' — Covariance matrix

nancov(*X*) (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

'IncludeTies' — Tie inclusion flag

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether predict includes all the neighbors whose distance values are equal to the *K*th smallest distance. If **IncludeTies** is true, predict includes all these neighbors. Otherwise, predict uses exactly *K* neighbors.

Example: 'IncludeTies', true

Data Types: logical

'NSMethod' — Nearest neighbor search method

'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- `'kdtree'` — Create and use a *kd*-tree to find nearest neighbors. `'kdtree'` is valid when the distance metric is one of the following:
 - `'euclidean'`
 - `'cityblock'`
 - `'minkowski'`
 - `'chebychev'`
- `'exhaustive'` — Use the exhaustive search algorithm. The distance values from all points in *X* to each point in *Y* are computed to find nearest neighbors.

The default is `'kdtree'` when *X* has 10 or fewer columns, *X* is not sparse, and the distance metric is a `'kdtree'` type; otherwise, `'exhaustive'`.

Example: `'NSMethod', 'exhaustive'`

'PredictorNames' — Predictor variable names

cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply *X* and *Y*, then you can use `'PredictorNames'` to give the predictor variables in *X* names.
 - The order of the names in `PredictorNames` must correspond to the column order of *X*. That is, `PredictorNames{1}` is the name of $X(:, 1)$, `PredictorNames{2}` is the name of $X(:, 2)$, and so on. Also, `size(X, 2)` and `numel(PredictorNames)` must be equal.
 - By default, `PredictorNames` is `{x1, x2, ...}`.
- If you supply *Tbl*, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitcknn` uses the predictor variables in `PredictorNames` and the response only in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It good practice to specify the predictors for training using one of `'PredictorNames'` or `formula` only.

Example: 'PredictorNames',
{'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth'}

Data Types: cell

'Prior' — Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in Y .
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	A structure S with two fields: <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as Y. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior', 'uniform'

Data Types: single | double | struct

'ResponseName' — Response variable name

'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName', 'response'

Data Types: char

'Scale' — Distance scale

nanstd(X) (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

'ScoreTransform' — Score transform function

'none' (default) | character vector | function handle

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a function handle or value in this table.

Value	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$

Value	Formula
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: function_handle | char

'Weights' — Observation weights

numeric vector of positive values | character vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response when training the model.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.

By default, Weights is ones($n, 1$), where n is the number of observations in X or Tbl.

Data Types: double | single | char

Cross Validation

'CrossVal' — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross validate later by passing `Mdl` to `crossval`.

Example: `'CrossVal','on'`

'CVPartition' — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the **Trained** property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: **CVPartition**, **Holdout**, **KFold**, or **Leaveout**.

Example: 'KFold', 5

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations, where n is `size(Mdl.X, 1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in the cells of an n -by-1 cell vector in the **Trained** property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: **CVPartition**, **Holdout**, **KFold**, or **Leaveout**.

Example: 'Leaveout', 'on'

Data Types: char

Hyperparameters**'Distance' — Distance metric**

character vector | function handle

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see NSMethod).

NSMethod	Distance Metric Names
exhaustive	Any distance metric of ExhaustiveSearcher
kdtree	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

This table includes valid distance metrics of ExhaustiveSearcher.

Distance Metric Names	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix C . The default value of C is the sample covariance matrix of X , as computed by <code>nancov(X)</code> . To specify a different value for C , use the 'Cov' name-value pair argument.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'Exponent' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S . The default value of S is the standard deviation computed from X , <code>S = nanstd(X)</code> . To specify another value for S , use the <code>Scale</code> name-value pair argument.

Distance Metric Names	Description
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	Distance function handle. <i>distfun</i> has the form <pre>function D2 = DISTFUN(ZI,ZJ) % calculation of distance ... where</pre> <ul style="list-style-type: none"> • ZI is a 1-by-N vector containing one row of X or Y. • ZJ is an M2-by-N matrix containing multiple rows of X or Y. • D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(J,:).

If you specify `CategoricalPredictors` as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

For definitions, see “Distance Metrics” on page 18-10.

Example: 'Distance', 'minkowski'

Data Types: `function_handle` | `char`

'DistanceWeight' — Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | `function handle`

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the values in this table.

Value	Description
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance ²
@ <i>fcn</i>	<i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).

Example: 'DistanceWeight', 'inverse'

Data Types: function_handle | char

'Exponent' — Minkowski distance exponent

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent', 3

Data Types: single | double

'NumNeighbors' — Number of nearest neighbors to find

1 (default) | positive integer value

Number of nearest neighbors in X to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

Example: 'NumNeighbors', 3

Data Types: single | double

'Standardize' — Flag to standardize predictors

false (default) | true

Flag to standardize the predictors, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize', true, then the software centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively.

The software does not standardize categorical predictors, and throws an error if all predictors are categorical.

You cannot simultaneously specify 'Standardize', 1 and either of 'Scale' or 'Cov'.

It is good practice to standardize the predictor data.

Example: 'Standardize', true

Data Types: logical

Hyperparameter Optimization

'OptimizeHyperparameters' — Parameters to optimize

'none' (default) | 'auto' | 'all' | cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as:

- 'none' — Do not optimize.
- 'auto' — Use {'Distance', 'NumNeighbors'}
- 'all' — Optimize all eligible parameters.
- Cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitcknn` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 29-3219. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note: `OptimizeHyperparameters` values override any values you set using other name-value pairs. For example, setting `OptimizeHyperparameters` to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitcknn` are:

- `Distance` — `fitcknn` searches among 'cityblock', 'chebychev', 'correlation', 'cosine', 'euclidean', 'hamming', 'jaccard', 'mahalanobis', 'minkowski', 'seuclidean', and 'spearman'.
- `DistanceWeight` — `fitcknn` searches among 'equal', 'inverse', and 'squaredinverse'.
- `Exponent` — `fitcknn` searches among positive real values, by default in the range [0.5,3].
- `NumNeighbors` — `fitcknn` searches among positive integer values, by default log-scaled in the range [1, max(2,round(NumObservations/2))].
- `Standardize` — `fitcknn` searches among the values 'true' and 'false'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcknn',meas,species);
params(1).Range = [1,20];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression, and the misclassification rate for classification. To control the iterative display, set the `HyperparameterOptimizationOptions` name-value pair, `Verbose` field. To control the plots, set the `HyperparameterOptimizationOptions` name-value pair, `ShowPlots` field.

For an example, see “Optimize Fitted KNN Classifier” on page 29-1958.

Example: 'auto'

Data Types: char | cell

'HyperparameterOptimizationOptions' — Options for optimization

structure

Options for optimization, specified as a structure. Modifies the effect of the `OptimizeHyperparameters` name-value pair. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling</p>	'bayesopt'

Field Name	Values	Default
	without replacement from the grid. After optimization, you can get a table in grid order by using the <code>commandsortrows(Mdl.ParameterOptim</code>	
AcquisitionFunc	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>For details, see the <code>bayesopt</code> AcquisitionFunctionName name-value pair, or “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEva	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
NumGridDivision	For 'gridsearch', the number of values in each dimension. Can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. Ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , plots the best objective function value against iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is 'bayesopt', then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>

Field Name	Values	Default
SaveIntermediate	Logical value indicating whether to save results when <code>Optimizer</code> is 'bayesopt'. If <code>true</code> , overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a <code>BayesianOptimization</code> object.	false
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesoptVerbose</code> name-value pair.	1
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code>	Kfold = 5
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example: `struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

Mdl — Trained *k*-nearest neighbor classification model

ClassificationKNN model object | ClassificationPartitionedModel cross-validated model object

Trained *k*-nearest neighbor classification model, returned as a ClassificationKNN model object or a ClassificationPartitionedModel cross-validated model object.

If you set any of the name-value pair arguments KFold, Holdout, CrossVal, or CVPartition, then Mdl is a ClassificationPartitionedModel cross-validated model object. Otherwise, Mdl is a ClassificationKNN model object.

To reference properties of Mdl, use dot notation. For example, to display the distance metric at the Command Window, enter `Mdl.Distance`.

Definitions

Prediction

ClassificationKNN predicts the classification of a point *Xnew* using a procedure equivalent to this:

- 1 Find the NumNeighbors points in the training set *X* that are nearest to *Xnew*.
- 2 Find the NumNeighbors response values *Y* to those nearest points.
- 3 Assign the classification label *Ynew* that has the largest posterior probability among the values in *Y*.

For details, see “Posterior Probability” on page 29-4877 in the predict documentation.

Algorithms

- NaNs or <undefined>s indicate missing observations. The following describes the behavior of fitcknn when the data set or weights contain missing observations.
 - If any value of *Y* or any weight is missing, then fitcknn removes those values from *Y*, the weights, and the corresponding rows of *X* from the data. The software renormalizes the weights to sum to 1.

- If you specify to standardize predictors ('Standardize', 1) or the standardized Euclidean distance ('Distance', 'seuclidean') without a scale, then `fitcknn` removes missing observations from individual predictors before computing the mean and standard deviation. In other words, the software implements `nanmean` and `nanstd` on each predictor.
- If you specify the Mahalanobis distance ('Distance', 'mahalanobis') without its covariance matrix, then `fitcknn` removes rows of X that contain at least one missing value. In other words, the software implements `nancov` on the predictor matrix X .
- Suppose that you set 'Standardize', 1.
 - If you also specify `Prior` or `Weights`, then the software takes the observation weights into account. Specifically, the weighted mean of predictor j is

$$\bar{x}_j = \sum_{B_j} w_k x_{jk}$$

and the weighted standard deviation is

$$s_j = \sum_{B_j} w_k (x_{jk} - \bar{x}_j),$$

where B_j is the set of indices k for which x_{jk} and w_k are not missing.

- If you also set 'Distance', 'mahalanobis' or 'Distance', 'seuclidean', then you cannot specify `Scale` or `Cov`. Instead, the software:
 - 1 Computes the means and standard deviations of each predictor
 - 2 Standardizes the data using the results of step 1
 - 3 Computes the distance parameter values using their respective default.
- If you specify `Scale` and either of `Prior` or `Weights`, then the software scales observed distances by the weighted standard deviations.
- If you specify `Cov` and either of `Prior` or `Weights`, then the software applies the weighted covariance matrix to the distances. In other words,

$$\text{Cov} = \frac{\sum_B w_j}{\left(\sum_B w_j\right)^2 - \sum_B w_j^2} \sum_B w_j (x_j - \bar{x})' (x_j - \bar{x}),$$

where B is the set of indices j for which the observation x_j does not have any missing values and w_j is not missing.

Alternatives

Although `fitcknn` can train a multiclass KNN classifier, you can reduce a multiclass learning problem to a series of KNN binary learners using `fitcecoc`.

fitclinear

Fit linear classification model to high-dimensional data

`fitclinear` trains linear classification models for two-class (binary) learning with high-dimensional, full or sparse predictor data. Available linear classification models include regularized support vector machines (SVM) and logistic regression models. `fitclinear` minimizes the objective function using techniques that reduce computing time (e.g., stochastic gradient descent).

A high-dimensional data set includes many predictor variables. Although such a data set can consume a significant fraction of memory, it must fit in the MATLAB Workspace. For low- through medium-dimensional predictor data sets, see “Alternatives for Lower-Dimensional Data” on page 19-2.

To train a linear classification model for multiclass learning by combining SVM or logistic regression binary classifiers using error-correcting output codes, see `fitcecoc`.

Syntax

```
Mdl = fitclinear(X,Y)
Mdl = fitclinear(X,Y,Name,Value)
[Mdl,FitInfo] = fitclinear(____)
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitclinear(____)
```

Description

`Mdl = fitclinear(X,Y)` returns a trained linear classification model object that contains the results of fitting a binary support vector machine to the predictors `X` and class labels `Y`.

`Mdl = fitclinear(X,Y,Name,Value)` returns a trained linear classification model with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify that the columns of the predictor matrix correspond to observations, implement logistic regression, or specify to cross-validate. It is good practice to cross-validate using the `Kfold Name,Value` pair argument. The cross-validation results determine how well the model generalizes.

[Mdl,FitInfo] = fitlinear(___) also returns optimization details using any of the previous syntaxes. You cannot request FitInfo for cross-validated models.

[Mdl,FitInfo,HyperparameterOptimizationResults] = fitlinear(___) also returns hyperparameter optimization details when you pass an OptimizeHyperparameters name-value pair.

Examples

Train Linear Classification Model

Train a binary, linear classification model using support vector machines, dual SGD, and ridge regularization.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Train the algorithm using the entire data set. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

```
rng(1); % For reproducibility
[Mdl,FitInfo] = fitlinear(X,Ystats)
```

Mdl =

```
ClassificationLinear
  ResponseName: 'Y'
   ClassNames: [0 1]
  ScoreTransform: 'none'
           Beta: [34023×1 double]
           Bias: -1.0059
```

```
Lambda: 3.1674e-05  
Learner: 'svm'
```

```
FitInfo =
```

```
struct with fields:
```

```
    Lambda: 3.1674e-05  
    Objective: 5.3783e-04  
    PassLimit: 10  
    NumPasses: 10  
    BatchLimit: []  
    NumIterations: 238561  
    GradientNorm: NaN  
    GradientTolerance: 0  
    RelativeChangeInBeta: 0.0562  
    BetaTolerance: 1.0000e-04  
    DeltaGradient: 1.4582  
    DeltaGradientTolerance: 1  
    TerminationCode: 0  
    TerminationStatus: {'Maximal number of iterations has been reached.'}  
    Alpha: [31572×1 double]  
    History: []  
    FitTime: 0.1909  
    Solver: {'dual'}
```

`Mdl` is a `ClassificationLinear` model. You can pass `Mdl` and the training or new data to `loss` to inspect the in-sample classification error. Or, you can pass `Mdl` and new predictor data to `predict` to predict class labels for new observations.

`FitInfo` is a structure array containing, among other things, the termination status (`TerminationStatus`) and how long the solver took to fit the model to the data (`FitTime`). It is good practice to use `FitInfo` to determine whether optimization-termination measurements are satisfactory. Because training time is small, you can try to retrain the model, but increase the number of passes through the data. This can improve measures like `DeltaGradient`.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, implement 5-fold cross-validation.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Estimate the coefficients using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
X = X';
rng(10); % For reproducibility
CVMdl = fitlinear(X, Ystats, 'ObservationsIn', 'columns', 'KFold', 5, ...
    'Learner', 'logistic', 'Solver', 'sparsa', 'Regularization', 'lasso', ...
    'Lambda', Lambda, 'GradientTolerance', 1e-8)
```

```
numCLModels = numel(CVMdl.Trained)
```

```
CVMdl =
```

```
classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 5
  Partition: [1×1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'
```

```
numCLModels =  
    5
```

`CVMD1` is a `ClassificationPartitionedLinear` model. Because `fitclinear` implements 5-fold cross-validation, `CVMD1` contains 5 `ClassificationLinear` models that the software trains on each fold.

Display the first trained linear classification model.

```
Md11 = CVMD1.Trained{1}
```

```
Md11 =  
    ClassificationLinear  
        ResponseName: 'Y'  
        ClassNames: [0 1]  
        ScoreTransform: 'logit'  
            Beta: [34023×11 double]  
            Bias: [1×11 double]  
            Lambda: [1×11 double]  
            Learner: 'logistic'
```

`Md11` is a `ClassificationLinear` model object. `fitclinear` constructed `Md11` by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of `Md11` as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated classification error.

```
ce = kfoldLoss(CVMD1);
```

Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitlinear(X,Ystats,'ObservationsIn','columns',...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...  
    'Lambda',Lambda,'GradientTolerance',1e-8);  
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;  
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...  
    log10(Lambda),log10(numNZCoeff));  
hL1.Marker = 'o';  
hL2.Marker = 'o';  
ylabel(h(1),'log_{10} classification error')  
ylabel(h(2),'log_{10} nonzero-coefficient frequency')  
xlabel('log_{10} Lambda')  
title('Test-Sample Statistics')  
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from Mdl with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

MdlFinal is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass MdlFinal and the new data to `predict`.

Optimize Linear Classifier

This example shows how to minimize the cross-validation error in a linear classifier using `fitclinear`. The example uses the NLP data set.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. Identify the relevant labels.

```
X = X';
Ystats = Y == 'stats';
```

Optimize the classification using the 'auto' parameters.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng default
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns','Solver','sparsa',...
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',...
    struct('AcquisitionFunctionName','expected-improvement-plus'))
```

Input Arguments

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix.

The length of `Y` and the number of observations in `X` must be equal.

Note: If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn'`, `'columns'`, then you might experience a significant reduction in optimization-execution time.

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels to which the classification linear model is trained, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

- `Y` must contain exactly two distinct classes. For multiclass learning, see `fitcecoc`.
- If `Y` is a character array, then each element must correspond to one row of the array.
- The length of `Y` and the number of observations in `X` must be equal.
- It is good practice to specify the class order using the `ClassNames` name-value pair argument.

Data Types: `char` | `cell` | `categorical` | `logical` | `single` | `double`

Note `fitclinear` removes missing observations, that is, observations with any of these characteristics:

- NaN, empty character vector (`' '`), and `<undefined>` elements in the response (`Y` or `ValidationData{2}`)
- At least one NaN value in a predictor observation (row in `X` or `ValidationData{1}`)
- NaN value or 0 weight (`Weights` or `ValidationData{3}`)

For memory-usage economy, it is best practice to remove observations containing missing values from your training data manually before training.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Note: You cannot use any cross-validation name-value pair along with `OptimizeHyperparameters`. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair.

Example:

'ObservationsIn', 'columns', 'Learner', 'logistic', 'CrossVal', 'on' specifies that the columns of the predictor matrix corresponds to observations, to implement logistic regression, to implement 10-fold cross-validation.

Linear Classification Options

'Lambda' — Regularization term strength

'auto' (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto', a nonnegative scalar, or a vector of nonnegative values.

- For 'auto', $\text{Lambda} = 1/n$.
 - If you specify a cross-validation, name-value pair argument (e.g., `CrossVal`), then n is the number of in-fold observations.
 - Otherwise, n is the training sample size.
- For a vector of nonnegative values, the software sequentially optimizes the objective function for each distinct value in `Lambda` in ascending order.
 - If `Solver` is 'sgd' or 'asgd' and `Regularization` is 'lasso', then the software does not use the previous coefficient estimates as a warm start for the next optimization iteration. Otherwise, the software uses warm starts.
 - If `Regularization` is 'lasso', then any coefficient estimate of 0 retains its value when the software optimizes using subsequent values in `Lambda`.

Returns coefficient estimates for all optimization iterations.

Example: 'Lambda', 10.^(-(10:-2:2))

Data Types: char | double | single

'Learner' — Linear classification model type

'svm' (default) | 'logistic'

Linear classification model type, specified as the comma-separated pair consisting of 'Learner' and 'svm' or 'logistic'.

In this table, $f(x) = \beta'x + b$.

- β is a vector of p coefficients.
- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Response range	Loss function
'svm'	Support vector machine	$y \in \{-1, 1\}$; 1 for the positive class, and -1 otherwise.	Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$
'logistic'	Logistic regression	Same as 'svm'	Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$

Example: 'Learner', 'logistic'

Data Types: char

'ObservationsIn' — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

Note: If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Data Types: char

'Regularization' — Complexity penalty type

'lasso' | 'ridge'

Complexity penalty type, specified as the comma-separated pair consisting of 'Regularization' and 'lasso' or 'ridge'.

The software composes the objective function for minimization from the sum of the average loss function (see **Learner**) and the regularization term in this table.

Value	Description
'lasso'	Lasso (L1) penalty: $\lambda \sum_{j=1}^p \beta_j $
'ridge'	Ridge (L2) penalty: $\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$

To specify the regularization term strength, which is λ in the expressions, use **Lambda**.

The software excludes the bias term (β_0) from the regularization penalty.

If **Solver** is 'sparsa', then the default value of **Regularization** is 'lasso'. Otherwise, the default is 'ridge'.

Tip:

- For predictor variable selection, specify 'lasso'.
- For optimization accuracy, specify 'ridge'.

Example: 'Regularization', 'lasso'

Data Types: char

'Solver' — Objective function minimization technique

'sgd' | 'asgd' | 'dual' | 'bfgs' | 'lbfgs' | 'sparsa' | cell vector of character vectors

Objective function minimization technique, specified as the comma-separated pair consisting of 'Solver' and a value or cell vector of values in this table.

Value	Description	Restrictions
'sgd'	Stochastic gradient descent (SGD) [5][3]	
'asgd'	Average stochastic gradient descent (ASGD) [8]	
'dual'	Dual SGD for SVM [2][7]	Regularization must be 'ridge' and Learner must be 'svm'.
'bfgs'	Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [4]	Inefficient if X is very high-dimensional.
'lbfgs'	Limited-memory BFGS (LBFGS) [4]	Regularization must be 'ridge'.
'sparsa'	Sparse Reconstruction by Separable Approximation (SpaRSA) [6]	Regularization must be 'lasso'.

If you specify:

- A ridge penalty (see **Regularization**) and X contains 100 or fewer predictor variables, then the default solver is 'bfgs'.
- An SVM model (see **Learner**), a ridge penalty, and X contains more than 100 predictor variables, then the default solver is 'dual'.
- A lasso penalty and X contains 100 or fewer predictor variables, then the default solver is 'sparsa'.

Otherwise, the default solver is 'sgd'.

If you specify a cell vector of solver names, then the software uses all solvers in the specified order for each **Lambda**.

For more details on which solver to choose, see “Tips” on page 29-2023.

Example: 'Solver', {'sgd', 'lbfgs'}

Data Types: char | cell

'Beta' — Initial linear coefficient estimateszeros($p, 1$) (default) | numeric vector | numeric matrix

Initial linear coefficient estimates (β), specified as the comma-separated pair consisting of **'Beta'** and a p -dimensional numeric vector or a p -by- L numeric matrix. p is the number of predictor variables in X and L is the number of regularization-strength values (for more details, see **Lambda**).

- If you specify a p -dimensional vector, then the software optimizes the objective function L times using this process.
 - 1 The software optimizes using **Beta** as the initial value and the minimum value of **Lambda** as the regularization strength.
 - 2 The software optimizes again using the resulting estimate from the previous optimization as a warm start, and the next smallest value in **Lambda** as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in **Lambda**.
- If you specify a p -by- L matrix, then the software optimizes the objective function L times. At iteration j , the software uses **Beta**($:$, j) as the initial value and, after it sorts **Lambda** in ascending order, uses **Lambda**(j) as the regularization strength.

If you set **'Solver'**, **'dual'**, then the software ignores **Beta**.

Data Types: single | double

'Bias' — Initial intercept estimate

numeric scalar | numeric vector

Initial intercept estimate (b), specified as the comma-separated pair consisting of **'Bias'** and a numeric scalar or an L -dimensional numeric vector. L is the number of regularization-strength values (for more details, see **Lambda**).

- If you specify a scalar, then the software optimizes the objective function L times using this process.
 - 1 The software optimizes using **Bias** as the initial value and the minimum value of **Lambda** as the regularization strength.
 - 2 The uses the resulting estimate as a warm start to the next optimization iteration, and uses the next smallest value in **Lambda** as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in **Lambda**.

- If you specify an L -dimensional vector, then the software optimizes the objective function L times. At iteration j , the software uses $\text{Bias}(j)$ as the initial value and, after it sorts Lambda in ascending order, uses $\text{Lambda}(j)$ as the regularization strength.
- By default:
 - If `Learner` is 'logistic', then let g_j be 1 if $Y(j)$ is the positive class, and -1 otherwise. `Bias` is the weighted average of the g for training or, for cross-validation, in-fold observations.
 - If `Learner` is 'svm', then `Bias` is 0.

Data Types: single | double

'FitBias' — Linear model intercept inclusion flag

true (default) | false

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of 'FitBias' and true or false.

Value	Description
true	The software includes the bias term b in the linear model, and then estimates it.
false	The software sets $b = 0$ during estimation.

Example: 'FitBias', false

Data Types: logical

'PostFitBias' — Flag to fit linear model intercept after optimization

false (default) | true

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of 'PostFitBias' and true or false.

Value	Description
false	The software estimates the bias term b and the coefficients β during optimization.

Value	Description
true	To estimate b , the software: <ol style="list-style-type: none"> 1 Estimates β and b using the model 2 Estimates classification scores 3 Refits b by placing the threshold on the classification scores that attains maximum accuracy

If you specify `true`, then `FitBias` must be true.

Example: `'PostFitBias', true`

Data Types: `logical`

'Verbose' – Verbosity level

0 (default) | nonnegative integer

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and a nonnegative integer. `Verbose` controls the amount of diagnostic information `fitlinear` displays at the command line.

Value	Description
0	<code>fitlinear</code> does not display diagnostic information.
1	<code>fitlinear</code> periodically displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. <code>FitInfo.History</code> contains the diagnostic information.
Any other positive integer	<code>fitlinear</code> displays and stores diagnostic information at each optimization iteration. <code>FitInfo.History</code> contains the diagnostic information.

Example: `'Verbose', 1`

Data Types: `double` | `single`

SGD and ASGD Solver Options

'BatchSize' — Mini-batch size

positive integer

Mini-batch size, specified as the comma-separated pair consisting of 'BatchSize' and a positive integer. At each iteration, the software estimates the subgradient using BatchSize observations from the training data.

- If X is a numeric matrix, then the default value is 10.
- If X is a sparse matrix, then the default value is $\max([10, \text{ceil}(\text{sqrt}(\text{ff}))])$, where $\text{ff} = \text{numel}(X) / \text{nnz}(X)$ (the *fullness factor* of X).

Example: 'BatchSize', 100

Data Types: single | double

'LearnRate' — Learning rate

positive scalar

Learning rate, specified as the comma-separated pair consisting of 'LearnRate' and a positive scalar. LearnRate specifies how many steps to take per iteration. At each iteration, the gradient specifies the direction and magnitude of each step.

- If Regularization is 'ridge', then LearnRate specifies the initial learning rate γ_0 . The software determines the learning rate for iteration t , γ_t , using

$$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$

- λ is the value of Lambda.
- If Solver is 'sgd', then $c = 1$.
- If Solver is 'asgd', then c is 0.75 [7].
- If Regularization is 'lasso', then, for all iterations, LearnRate is constant.

By default, LearnRate is $1 / \text{sqrt}(1 + \max(\text{sum}(X.^2, \text{obsDim})))$, where obsDim is 1 if the observations compose the columns of the predictor data X , and 2 otherwise.

Example: 'LearnRate', 0.01

Data Types: `single` | `double`

'OptimizeLearnRate' — Flag to decrease learning rate

`true` (default) | `false`

Flag to decrease the learning rate when the software detects divergence (that is, over-stepping the minimum), specified as the comma-separated pair consisting of `'OptimizeLearnRate'` and `true` or `false`.

If `OptimizeLearnRate` is `'true'`, then:

- 1 For the few optimization iterations, the software starts optimization using `LearnRate` as the learning rate.
- 2 If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.
- 3 The software iterates step 2 until the objective function decreases.

Example: `'OptimizeLearnRate', true`

Data Types: `logical`

'TruncationPeriod' — Number of mini-batches between lasso truncation runs

10 (default) | positive integer

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of `'TruncationPeriod'` and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing $k = \text{TruncationPeriod}$ mini-batches, the software truncates the estimated coefficient j using

$$\hat{\beta}_j^* = \begin{cases} \hat{\beta}_j - u_t & \text{if } \hat{\beta}_j > u_t \\ 0 & \text{if } |\hat{\beta}_j| \leq u_t \\ \hat{\beta}_j + u_t & \text{if } \hat{\beta}_j < -u_t \end{cases}$$

- For SGD, $\hat{\beta}_j$ is the estimate of coefficient j after processing k mini-batches. $u_t = k\gamma_t\lambda$. γ_t is the learning rate at iteration t . λ is the value of `Lambda`.

- For ASGD, $\hat{\beta}_j$ is the averaged estimate coefficient j after processing k mini-batches, $u_t = k\lambda$.

If `Regularization` is `'ridge'`, then the software ignores `TruncationPeriod`.

Example: `'TruncationPeriod', 100`

Data Types: `single` | `double`

Other Classification Options

'ClassNames' — Names of classes to use for training

categorical array | cell array of character vectors | character array | logical vector | numeric vector

Names of classes to use for training, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` must be the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a', 'b', 'c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames', {'a', 'c'}`.

The default is the set of all distinct class names in `Y`.

Example: `'ClassNames', {'b', 'g'}`

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

'Cost' — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure. If you specify:

- The square matrix `Cost`, then `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, also specify the `ClassNames` name-value pair argument.
- The structure `S`, then it must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
 - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

The default is `ones(K) - eye(K)`, where `K` is the number of distinct classes.

`fitclinear` uses `Cost` to adjust the prior class probabilities specified in `Prior`. Then, `fitclinear` uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: 'Cost', [0 1 2 ; 1 0 2; 2 2 0]

Data Types: double | single | struct

'Prior' — Prior probabilities

'empirical' (default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a character vector, numeric vector, or a structure.

This table summarizes the available options for setting prior probabilities.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in <code>Y</code> .
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>SVMMModel.ClassNames</code> or specify the

Value	Description
	order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	<p>A structure <code>S</code> with two fields:</p> <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

`fitclinear` normalizes the prior probabilities in `Prior` to sum to 1.

```
Example: struct('ClassNames',
{{'setosa','versicolor','virginica'}},'ClassProbs',1:3)
```

Data Types: char | double | single | struct

'Weights' — Observation weights

numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values. `fitclinear` weighs the observations in `X` with the corresponding value in `Weights`. The size of `Weights` must equal the number of observations in `X`.

`fitclinear` normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n,1)`, where n is the number of observations in `X`.

Data Types: double | single

Cross-Validation Options

'CrossVal' — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, or `KFold`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Example: `'Crossval','on'`

Data Types: `char`

'CVPartition' — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', ρ` , then the software:

- 1 Randomly reserves $\rho*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

Example: 'KFold',8

Data Types: single | double

SGD and ASGD Convergence Controls

'BatchLimit' — Maximal number of batches

positive integer

Maximal number of batches to process, specified as the comma-separated pair consisting of 'BatchLimit' and a positive integer. When the software processes `BatchLimit` batches, it terminates optimization.

- By default:
 - The software passes through the data `PassLimit` times.
 - If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is `ceil(1e6/BatchSize)`. `BatchSize` is the value of the 'BatchSize' name-value pair argument.
- If you specify 'BatchLimit' and 'PassLimit', then the software chooses the argument that results in processing the fewest observations.
- If you specify 'BatchLimit' but not 'PassLimit', then the software processes enough batches to complete up to one entire pass through the data.

Example: 'BatchLimit',100

Data Types: single | double

'BetaTolerance' — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = \begin{bmatrix} \beta_t' & b_t \end{bmatrix}$, that is, the vector of the coefficients and the bias term at optimization

iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: 'BetaTolerance', 1e-6

Data Types: single | double

'NumCheckConvergence' — Number of batches to process before next convergence check

positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

To specify the batch size, see `BatchSize`.

The software checks for convergence about 10 times per pass through the entire data set by default.

Example: 'NumCheckConvergence', 100

Data Types: single | double

'PassLimit' — Maximal number of passes

1 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.

`fitcllinear` processes all observations when it completes one pass through the data.

When `fitcllinear` passes through the data `PassLimit` times, it terminates optimization.

If you specify `'BatchLimit'` and `'PassLimit'`, then `fitclinear` chooses the argument that results in processing the fewest observations.

Example: `'PassLimit',5`

Data Types: `single` | `double`

'ValidationData' — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of `'ValidationData'` and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 29-2024. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- `ValidationData{2}` and `Y` must be the same data type. The set of all distinct labels of `ValidationData{2}` must be a subset of all distinct labels of `Y`.
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

Dual SGD Convergence Controls

'BetaTolerance' — Relative tolerance on linear coefficients and bias term

`1e-4` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = \begin{bmatrix} \beta_t' & b_t \end{bmatrix}$, that is, the vector of the coefficients and the bias term at optimization

iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify `DeltaGradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: 'BetaTolerance', 1e-6

Data Types: single | double

'DeltaGradientTolerance' — Gradient-difference tolerance

1 (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions violators, specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar.

- If the magnitude of the KKT violators is less than `DeltaGradientTolerance`, then the software terminates optimization.
- If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: 'DeltaGapTolerance', 1e-2

Data Types: double | single

'NumCheckConvergence' — Number of passes through entire data set to process before next convergence check

5 (default) | positive integer

Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

Example: 'NumCheckConvergence', 100

Data Types: single | double

'PassLimit' — Maximal number of passes

10 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data `PassLimit` times, it terminates optimization.

Example: `'PassLimit',5`

Data Types: `single` | `double`

'ValidationData' — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of `'ValidationData'` and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 29-2024. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- `ValidationData{2}` and `Y` must be the same data type. The set of all distinct labels of `ValidationData{2}` must be a subset of all distinct labels of `Y`.
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

BFGS, LBFGS, and SpARSA Convergence Controls

'BetaTolerance' — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = \begin{bmatrix} \beta_t' & b_t \end{bmatrix}$, that is, the vector of the coefficients and the bias term at optimization

iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify **GradientTolerance**, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in **Solver**, then optimization terminates. Otherwise, the software uses the next solver specified in **Solver**.

Example: 'BetaTolerance', 1e-6

Data Types: single | double

'GradientTolerance' — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let ∇_{L_t} be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla_{L_t}\|_\infty = \max|\nabla_{L_t}| < \text{GradientTolerance}$, then optimization terminates.

If you also specify **BetaTolerance**, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in **Solver**.

Example: 'GradientTolerance', 1e-5

Data Types: single | double

'HessianHistorySize' — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest HessianHistorySize iterations.

The software does not support 'HessianHistorySize' for SpaRSA.

Example: 'HessianHistorySize', 10

Data Types: single | double

'IterationLimit' — Maximal number of optimization iterations

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. `IterationLimit` applies to these values of `Solver`: 'bfgs', 'lbfgs', and 'sparsa'.

Example: 'IterationLimit', 500

Data Types: single | double

'ValidationData' — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 29-2024. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. The number of observations in both sets can vary.

- `ValidationData{2}` and `Y` must be the same data type. The set of all distinct labels of `ValidationData{2}` must be a subset of all distinct labels of `Y`.
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

Hyperparameter Optimization

'OptimizeHyperparameters' — Parameters to optimize

'none' (default) | 'auto' | 'all' | cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as:

- 'none' — Do not optimize.
- 'auto' — Use {'Lambda', 'Learner'}
- 'all' — Optimize all eligible parameters.
- Cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of hyperparameters

The optimization attempts to minimize the cross-validation loss (error) for `fitlinear` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 29-3219. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note: `OptimizeHyperparameters` values override any values you set using other name-value pairs. For example, setting `OptimizeHyperparameters` to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitlinear` are:

- **Lambda** — `fitlinear` searches among positive values, by default log-scaled in the range $[1e-5/\text{NumObservations}, 1e5/\text{NumObservations}]$.
- **Learner** — `fitlinear` searches among 'svm' and 'logistic'.
- **Regularization** — `fitlinear` searches among 'ridge' and 'lasso'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitlinear',meas,species);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression, and the misclassification rate for classification. To control the iterative display, set the `HyperparameterOptimizationOptions` name-value pair, `Verbose` field. To control the plots, set the `HyperparameterOptimizationOptions` name-value pair, `ShowPlots` field.

For an example, see “Optimize Linear Classifier” on page 29-1991.

Example: 'auto'

Data Types: char | cell

'HyperparameterOptimizationOptions' — Options for optimization

structure

Options for optimization, specified as a structure. Modifies the effect of the `OptimizeHyperparameters` name-value pair. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. • 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 	'bayesopt'

Field Name	Values	Default
	<ul style="list-style-type: none"> 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the <code>commandsortrows(Mdl.ParameterOptim.</code></p>	
AcquisitionFunction	<ul style="list-style-type: none"> 'expected-improvement-per-second-plus' 'expected-improvement' 'expected-improvement-plus' 'expected-improvement-per-second' 'lower-confidence-bound' 'probability-of-improvement' <p>For details, see the <code>bayesopt</code> <code>AcquisitionFunctionName</code> name-value pair, or “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
NumGridDivisions	For 'gridsearch', the number of values in each dimension. Can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. Ignored for categorical variables.	10

Field Name	Values	Default
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , plots the best objective function value against iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is <code>'bayesopt'</code> , then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediate	Logical value indicating whether to save results when <code>Optimizer</code> is <code>'bayesopt'</code> . If <code>true</code> , overwrites a workspace variable named <code>'BayesoptResults'</code> at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesoptVerbose</code> name-value pair.	1
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <p><code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.</p>	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code>	<code>Kfold = 5</code>

Field Name	Values	Default
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example: `struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

Mdl — Trained linear classification model

`ClassificationLinear` model object | `ClassificationPartitionedLinear` cross-validated model object

Trained linear classification model, returned as a `ClassificationLinear` model object or `ClassificationPartitionedLinear` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedLinear` cross-validated model object. Otherwise, `Mdl` is a `ClassificationLinear` model object.

To reference properties of `Mdl`, use dot notation. For example, enter `Mdl.Beta` in the Command Window to display the vector or matrix of estimated coefficients.

Note: Unlike other classification models, and for economical memory usage, `ClassificationLinear` and `ClassificationPartitionedLinear` model objects do not store the training data or training process details (for example, convergence history).

FitInfo — Optimization details

structure array

Optimization details, returned as a structure array.

Fields specify final values or name-value pair argument specifications, for example, `Objective` is the value of the objective function when optimization terminates. Rows

of multidimensional fields correspond to values of `Lambda` and columns correspond to values of `Solver`.

This table describes some notable fields.

Field	Description														
<code>TerminationStatus</code>	<ul style="list-style-type: none"> Reason for optimization termination Corresponds to a value in <code>TerminationCode</code> 														
<code>FitTime</code>	Elapsed, wall-clock time in seconds														
<code>History</code>	<p>A structure array of optimization information for each iteration. The field <code>Solver</code> stores solver types using integer coding.</p> <table border="1"> <thead> <tr> <th>Integer</th> <th>Solver</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>SGD</td> </tr> <tr> <td>2</td> <td>ASGD</td> </tr> <tr> <td>3</td> <td>Dual SGD for SVM</td> </tr> <tr> <td>4</td> <td>LBFGS</td> </tr> <tr> <td>5</td> <td>BFGS</td> </tr> <tr> <td>6</td> <td>SpaRSA</td> </tr> </tbody> </table>	Integer	Solver	1	SGD	2	ASGD	3	Dual SGD for SVM	4	LBFGS	5	BFGS	6	SpaRSA
Integer	Solver														
1	SGD														
2	ASGD														
3	Dual SGD for SVM														
4	LBFGS														
5	BFGS														
6	SpaRSA														

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.History.Objective`.

It is good practice to examine `FitInfo` to assess whether convergence is satisfactory.

HyperparameterOptimizationResults — Description of the cross-validation optimization of hyperparameters

`BayesianOptimization` object | table of hyperparameters and associated values

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- 'bayesopt' (default) — Object of class `BayesianOptimization`
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Data Types: `table`

Definitions

Warm Start

A *warm start* is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

Tips

- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify 'ObservationsIn', 'columns'. As a result, you can experience a significant reduction in optimization-execution time.
- For better optimization accuracy if X is high-dimensional and Regularization is 'ridge', set any of these combinations for Solver:
 - 'sgd'
 - 'asgd'
 - 'dual' if Learner is 'svm'
 - {'sgd', 'lbfgs'}
 - {'asgd', 'lbfgs'}
 - {'dual', 'lbfgs'} if Learner is 'svm'

Other combinations can result in poor optimization accuracy.

- For better optimization accuracy if X is moderate- through low-dimensional and Regularization is 'ridge', set Solver to 'bfgs'.
- If Regularization is 'lasso', set any of these combinations for Solver:
 - 'sgd'

- 'asgd'
- 'sparsa'
- {'sgd', 'sparsa'}
- {'asgd', 'sparsa'}
- When choosing between SGD and ASGD, consider that:
 - SGD takes less time per iteration, but requires more iterations to converge.
 - ASGD requires fewer iterations to converge, but takes more time per iteration.
- If X has few observations, but many predictor variables, then:
 - Specify 'PostFitBias', true.
 - For SGD or ASGD solvers, set `PassLimit` to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.
- For SGD and ASGD solvers, `BatchSize` affects the rate of convergence.
 - If `BatchSize` is too small, then `fitclinear` achieves the minimum in many iterations, but computes the gradient per iteration quickly.
 - If `BatchSize` is too large, then `fitclinear` achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.
- Large learning rates (see `LearnRate`) speed up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.
- When using lasso penalties, experiment with various values of `TruncationPeriod`. For example, set `TruncationPeriod` to 1, 10, and then 100.
- For efficiency, `fitclinear` does not standardize predictor data. To standardize X , enter

```
X = bsxfun(@rdivide, bsxfun(@minus, X, mean(X, 2)), std(X, 0, 2));
```

The code requires that you orient the predictors and observations as the rows and columns of X , respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.

Algorithms

- If you specify `ValidationData`, then, during objective-function optimization:

- `fitlinear` estimates the validation loss of `ValidationData` periodically using the current model, and tracks the minimal estimate.
- When `fitlinear` estimates a validation loss, it compares the estimate to the minimal estimate.
- When subsequent, validation loss estimates exceed the minimal estimate five times, `fitlinear` terminates optimization.
- If you specify `ValidationData` and to implement a cross-validation routine (`CrossVal`, `CVPartition`, `Holdout`, or `KFold`), then:
 - 1** `fitlinear` randomly partitions `X` and `Y` according to the cross-validation routine that you choose.
 - 2** `fitlinear` trains the model using the training-data partition. During objective-function optimization, `fitlinear` uses `ValidationData` as another possible way to terminate optimization (for details, see the previous bullet).
 - 3** Once `fitlinear` satisfies a stopping criterion, it constructs a trained model based on the optimized linear coefficients and intercept.
 - a** If you implement k -fold cross-validation, and `fitlinear` has not exhausted all training-set folds, then `fitlinear` returns to Step 2 to train using the next training-set fold.
 - b** Otherwise, `fitlinear` terminates training, and then returns the cross-validated model.
 - 4** You can determine the quality of the cross-validated model. For example:
 - To determine the validation loss using the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldLoss`.
 - To predict observations on the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldPredict`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Tall Arrays

This function supports tall arrays for out-of-memory data with the limitations:

- Supported syntaxes for tall arrays X and Y are:
 - `obj = fitclinear(X,Y)`
 - `obj = fitclinear(__,Name,Value)`
- Some name-value pairs have different defaults compared to the in-memory `fitclinear` function. Supported name-value pairs, and any differences, are:
 - `'ObservationsIn'` — Supports only `'rows'`.
 - `'Lambda'` — Can be `'auto'` (default) or a scalar.
 - `'Learner'` — Can be `'svm'` (default) or `'logistic'`.
 - `'Regularization'` — Supports only `'ridge'`.

- 'Solver' — Supports only 'lbfgs'.
 - 'FitBias' — Supports only true.
 - 'Verbose' — Default value is 1.
 - 'Beta'
 - 'Bias'
 - 'ClassNames'
 - 'Cost'
 - 'Prior'
 - 'Weights' — Value must be a tall array.
 - 'HessianHistorySize'
 - 'BetaTolerance' — Default value is relaxed to $1e-3$.
 - 'GradientTolerance' — Default value is relaxed to $1e-3$.
 - 'IterationLimit' — Default value is relaxed to 20.
- For tall arrays, `fitlinear` implements LBFGS by distributing the calculation of the loss and gradient among different parts of the tall array at each iteration. Other solvers are not available for tall arrays.

When initial values for **Beta** and **Bias** are not given, `fitlinear` refines the initial estimates of the parameters by fitting the model locally to parts of the data and combining the coefficients by averaging.

For more information, see “Tall Arrays” (MATLAB).

Introduced in R2016a

fitcnb

Train multiclass naive Bayes model

Syntax

```
Mdl = fitcnb(Tbl,ResponseVarName)
```

```
Mdl = fitcnb(Tbl,formula)
```

```
Mdl = fitcnb(Tbl,Y)
```

```
Mdl = fitcnb(X,Y)
```

```
Mdl = fitcnb( ____,Name,Value)
```

Description

`Mdl = fitcnb(Tbl,ResponseVarName)` returns a multiclass naive Bayes model (`Mdl`), trained by the predictors in table `Tbl` and class labels in the variable `Tbl.ResponseVarName`.

`Mdl = fitcnb(Tbl,formula)` returns a multiclass naive Bayes model (`Mdl`), trained by the predictors in table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitcnb(Tbl,Y)` returns a multiclass naive Bayes model (`Mdl`), trained by the predictors in the table `Tbl` and class labels in the array `Y`.

`Mdl = fitcnb(X,Y)` returns a multiclass naive Bayes model (`Mdl`), trained by predictors `X` and class labels `Y`.

`Mdl = fitcnb(____,Name,Value)` returns a naive Bayes classifier with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify a distribution to model the data, prior probabilities for the classes, or the kernel smoothing window bandwidth.

Examples

Train a Naive Bayes Classifier

Load Fisher's iris data set.

```
load fisheriris
X = meas(:,3:4);
Y = species;
tabulate(Y)
```

Value	Count	Percent
setosa	50	33.33%
versicolor	50	33.33%
virginica	50	33.33%

The software can classify data with more than two classes using naive Bayes methods.

Train a naive Bayes classifier. It is good practice to specify the class order.

```
Mdl = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'})
```

Mdl =

```
ClassificationNaiveBayes
    ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: {'setosa' 'versicolor' 'virginica'}
        ScoreTransform: 'none'
        NumObservations: 150
        DistributionNames: {'normal' 'normal'}
        DistributionParameters: {3x2 cell}
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

By default, the software models the predictor distribution within each class using a Gaussian distribution having some mean and standard deviation. Use dot notation to display the parameters of a particular Gaussian fit, e.g., display the fit for the first feature within `setosa`.

```
setosaIndex = strcmp(Mdl.ClassNames, 'setosa');
estimates = Mdl.DistributionParameters{setosaIndex,1}
```

```
estimates =
    1.4620
    0.1737
```

The mean is 1.4620 and the standard deviation is 0.1737.

Plot the Gaussian contours.

```
figure
gscatter(X(:,1),X(:,2),Y);
h = gca;
cxlim = h.XLim;
cyylim = h.YLim;
hold on
Params = cell2mat(Mdl.DistributionParameters);
Mu = Params(2*(1:3)-1,1:2); % Extract the means
Sigma = zeros(2,2,3);
for j = 1:3
    Sigma(:,:,j) = diag(Params(2*j,:)).^2; % Create diagonal covariance matrix
    xlim = Mu(j,1) + 4*[1 -1]*sqrt(Sigma(1,1,j));
    ylim = Mu(j,2) + 4*[1 -1]*sqrt(Sigma(2,2,j));
    ezcontour(@(x1,x2)mvnpdf([x1,x2],Mu(j,:),Sigma(:,:,j)),[xlim ylim])
    % Draw contours for the multivariate normal distributions
end
h.XLim = cxlim;
h.YLim = cyylim;
title('Naive Bayes Classifier -- Fisher's Iris Data')
xlabel('Petal Length (cm)')
ylabel('Petal Width (cm)')
hold off
```

You can change the default distribution using the name-value pair argument 'DistributionNames'. For example, if some predictors are categorical, then you can specify that they are multivariate, multinomial random variables using 'DistributionNames', 'mvmn'.

Specify Prior Probabilities When Training Naive Bayes Classifiers

Construct a naive Bayes classifier for Fisher's iris data set. Also, specify prior probabilities during training.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
```

```
Y = species;  
classNames = {'setosa', 'versicolor', 'virginica'}; % Class order
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

By default, the prior class probability distribution is the relative frequency distribution of the classes in the data set, which in this case is 33% for each species. However, suppose you know that in the population 50% of the irises are setosa, 20% are versicolor, and 30% are virginica. You can incorporate this information by specifying this distribution as a prior probability during training.

Train a naive Bayes classifier. Specify the class order and prior class probability distribution.

```
prior = [0.5 0.2 0.3];  
Mdl = fitcnb(X,Y, 'ClassNames', classNames, 'Prior', prior)
```

```
Mdl =  
  
ClassificationNaiveBayes  
    ResponseName: 'Y'  
    CategoricalPredictors: []  
        ClassNames: {'setosa' 'versicolor' 'virginica'}  
    ScoreTransform: 'none'  
    NumObservations: 150  
    DistributionNames: {'normal' 'normal' 'normal' 'normal'}  
    DistributionParameters: {3x4 cell}
```

Mdl is a trained `ClassificationNaiveBayes` classifier, and some of its properties appear in the Command Window. The software treats the predictors as independent given a class, and, by default, fits them using normal distributions.

The naive Bayes algorithm does not use the prior class probabilities during training. Therefore, you can specify prior class probabilities after training using dot notation. For example, suppose that you want to see the difference in performance between a model that uses the default prior class probabilities and a model that uses `prior`.

Create a new naive Bayes model based on Mdl, and specify that the prior class probability distribution is an empirical class distribution.

```
defaultPriorMdl = Mdl;
```

```
FreqDist = cell2table(tabulate(Y));
defaultPriorMdl.Prior = FreqDist{: ,3};
```

The software normalizes the prior class probabilities to sum to 1.

Estimate the cross-validation error for both models using 10-fold cross validation.

```
rng(1); % For reproducibility
defaultCVMdl = crossval(defaultPriorMdl);
defaultLoss = kfoldLoss(defaultCVMdl)
CVMdl = crossval(Mdl);
Loss = kfoldLoss(CVMdl)
```

```
defaultLoss =
```

```
    0.0533
```

```
Loss =
```

```
    0.0340
```

Mdl performs better than defaultPriorMdl.

Specify Predictor Distributions for Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Train a naive Bayes classifier using every predictor. It is good practice to specify the class order.

```
Mdl1 = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'})
Mdl1.DistributionParameters
Mdl1.DistributionParameters{1,2}
```

```
Mdl1 =
```

```
ClassificationNaiveBayes
    ResponseName: 'Y'
```

```
CategoricalPredictors: []
      ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
      NumObservations: 150
      DistributionNames: {'normal' 'normal' 'normal' 'normal'}
      DistributionParameters: {3×4 cell}
```

```
ans =
```

```
3×4 cell array
```

```
[2×1 double] [2×1 double] [2×1 double] [2×1 double]
[2×1 double] [2×1 double] [2×1 double] [2×1 double]
[2×1 double] [2×1 double] [2×1 double] [2×1 double]
```

```
ans =
```

```
3.4280
0.3791
```

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. There are four predictors and three class levels. Each cell in `Mdl1.DistributionParameters` corresponds to a numeric vector containing the mean and standard deviation of each distribution, e.g., the mean and standard deviation for setosa iris sepal widths are 3.4280 and 0.3791, respectively.

Estimate the confusion matrix for `Mdl1`.

```
isLabels1 = resubPredict(Mdl1);
ConfusionMat1 = confusionmat(Y,isLabels1)
```

```
ConfusionMat1 =
```

```
50    0    0
 0   47    3
 0    3   47
```

Element (j, k) of `ConfusionMat1` represents the number of observations that the software classifies as k , but are truly in class j according to the data.

Retrain the classifier using the Gaussian distribution for predictors 1 and 2 (the sepal lengths and widths), and the default normal kernel density for predictors 3 and 4 (the petal lengths and widths).

```
Mdl2 = fitcnb(X,Y,...
    'Distribution',{'normal','normal','kernel','kernel'},...
    'ClassNames',{'setosa','versicolor','virginica'});
Mdl2.DistributionParameters{1,2}
```

```
ans =
```

```
    3.4280
    0.3791
```

The software does not train parameters to the kernel density. Rather, the software chooses an optimal width. However, you can specify a width using the 'Width' name-value pair argument.

Estimate the confusion matrix for Mdl2.

```
isLabels2 = resubPredict(Mdl2);
ConfusionMat2 = confusionmat(Y,isLabels2)
```

```
ConfusionMat2 =
```

```
    50     0     0
     0    47     3
     0     3    47
```

Based on the confusion matrices, the two classifiers perform similarly in the training sample.

Compare Classifiers Using Cross Validation

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Train and cross validate a naive Bayes classifier using the default options and k -fold cross validation. It is good practice to specify the class order.

```
CVMd11 = fitcnb(X,Y,...  
    'ClassNames',{ 'setosa', 'versicolor', 'virginica' },...  
    'CrossVal', 'on');
```

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. `CVMd11` is a `ClassificationPartitionedModel` model.

Create a default naive Bayes binary classifier template, and train an error-correcting, output codes multiclass model.

```
t = templateNaiveBayes();  
CVMd12 = fitcecoc(X,Y, 'CrossVal', 'on', 'Learners', t);
```

`CVMd12` is a `ClassificationPartitionedECOC` model. You can specify options for the naive Bayes binary learners using the same name-value pair arguments as for `fitcnb`.

Compare the out-of-sample k -fold classification error (proportion of misclassified observations).

```
classErr1 = kfoldLoss(CVMd11, 'LossFun', 'ClassifErr')  
classErr2 = kfoldLoss(CVMd12, 'LossFun', 'ClassifErr')
```

```
classErr1 =  
  
    0.0533
```

```
classErr2 =  
  
    0.0467
```

`Md12` has a lower generalization error.

Train Naive Bayes Classifiers Using Multinomial Predictors

Some spam filters classify an incoming email as spam based on how many times a word or punctuation (called tokens) occurs in an email. The predictors are the frequencies of particular words or punctuations in an email. Therefore, the predictors compose multinomial random variables.

This example illustrates classification using naive Bayes and multinomial predictors.

Create Training Data

Suppose you observed 1000 emails and classified them as spam or not spam. Do this by randomly assigning -1 or 1 to y for each email.

```
n = 1000;           % Sample size
rng(1);           % For reproducibility
Y = randsample([-1 1],n,true); % Random labels
```

To build the predictor data, suppose that there are five tokens in the vocabulary, and 20 observed tokens per email. Generate predictor data from the five tokens by drawing random, multinomial deviates. The relative frequencies for tokens corresponding to spam emails should differ from emails that are not spam.

```
tokenProbs = [0.2 0.3 0.1 0.15 0.25;...
              0.4 0.1 0.3 0.05 0.15]; % Token relative frequencies
tokensPerEmail = 20; % Fixed for convenience
X = zeros(n,5);
X(Y == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),sum(Y == 1));
X(Y == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),sum(Y == -1));
```

Train the Classifier

Train a naive Bayes classifier. Specify that the predictors are multinomial.

```
Mdl = fitcnb(X,Y,'Distribution','mn');
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

Assess the in-sample performance of Mdl by estimating the misclassification error.

```
isGenRate = resubLoss(Mdl,'LossFun','ClassifErr')
```

```
isGenRate =
    0.0200
```

The in-sample misclassification rate is 2%.

Create New Data

Randomly generate deviates that represent a new batch of emails.

```
newN = 500;
newY = randsample([-1 1],newN,true);
newX = zeros(newN,5);
newX(newY == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),...
    sum(newY == 1));
newX(newY == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),...
    sum(newY == -1));
```

Assess Classifier Performance

Classify the new emails using the trained naive Bayes classifier `Mdl`, and determine whether the algorithm generalizes.

```
oosGenRate = loss(Mdl,newX,newY)
```

```
oosGenRate =
    0.0261
```

The out-of-sample misclassification rate is 2.6% indicating that the classifier generalizes fairly well.

Optimize Naive Bayes Classifier

This example shows how to use the `OptimizeHyperparameters` name-value pair to minimize cross-validation loss in a naive Bayes classifier using `fitcnb`. The example uses Fisher's iris data.

Load Fisher's iris data.

```
load fisheriris
X = meas;
Y = species;
classNames = {'setosa','versicolor','virginica'};
```

Optimize the classification using the 'auto' parameters.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng default
Mdl = fitcnb(X,Y,'ClassNames',classNames,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
```

```
'expected-improvement-plus'))
```

Warning: It is recommended that you first standardize all numeric predictors when optimizing the Naive Bayes 'Width' parameter. Ignore this warning if you have done that.

Iter	Eval result	Objective	Objective runtime	BestSoFar (observed)	BestSoFar (estim.)	Distribution-Names

Input Arguments

Tb1 — Sample data
table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element must correspond to one row of the array.

It is good practice to specify the order of the classes using the `ClassNames` name-value pair argument.

Data Types: `char`

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of `'Y-X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char`

Y — Class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Class labels to which the naive Bayes classifier is trained, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Each element of `Y` defines the class membership of the corresponding row of `X`. `Y` supports K class levels.

If `Y` is a character array, then each row must correspond to one class label.

The length of `Y` and the number of rows of `X` must be equivalent.

Data Types: `cell` | `char` | `double` | `logical`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of `Y` and the number of rows of `X` must be equivalent.

Data Types: `double`

Note: The software treats NaN, empty character vector (`' '`), and `<undefined>` elements as missing values.

- If `Y` contains missing values, then the software removes them and the corresponding rows of `X`.
- If `X` contains any rows composed entirely of missing values, then the software removes those rows and the corresponding elements of `Y`.
- If `X` contains missing values and you set `'Distribution'`, `'mn'`, then the software removes those rows of `X` and the corresponding elements of `Y`.

- If a predictor is not represented in a class, that is, if all of its values are NaN within a class, then the software returns an error.

Removing rows of X and corresponding elements of Y decreases the effective training or cross-validation sample size.

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Note: You cannot use any cross-validation name-value pair along with `OptimizeHyperparameters`. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair.

Example: `'Distribution','mn','Prior','uniform','KSWidth',0.5` specifies that the data distribution is multinomial, the prior probabilities for all classes are equal, and the kernel smoothing window bandwidth for all classes is 0.5 units.

Naive Bayes Options

'DistributionNames' — Data distributions

'kernel' | 'mn' | 'mvmn' | 'normal' | cell array of character vectors

Data distributions `fitcnb` uses to model the data, specified as the comma-separated pair consisting of `'DistributionNames'` and a value in this table.

Value	Description
'kernel'	Kernel smoothing density estimate.
'mn'	Multinomial distribution. If you specify <code>mn</code> , then all features are components of a multinomial distribution. Therefore, you cannot include <code>'mn'</code> as an element of a cell

Value	Description
	array of character vectors. For details, see “Algorithms” on page 29-2061.
'mvmn'	Multivariate multinomial distribution. For details, see “Algorithms” on page 29-2061.
'normal'	Normal (Gaussian) distribution.

If you specify a character vector, then the software models all the features using that distribution. If you specify a 1-by- P cell array of character vectors, then the software models feature j using the distribution in element j of the cell array.

By default, the software sets all predictors specified as categorical predictors (using the `CategoricalPredictors` name-value pair argument) to 'mvmn'. Otherwise, the default distribution is 'normal'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: 'Distribution', 'mn'

Data Types: cell | char

'Kernel' — Kernel smoother type

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | cell array of character vectors

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and a character vector or cell array of character vectors.

This table summarizes the available options for setting the kernel smoothing density region. Let $I\{u\}$ denote the indicator function.

Value	Kernel	Formula
'box'	Box (uniform)	$f(x) = 0.5I\{ x \leq 1\}$
'epanechni	Epanechnikov	$f(x) = 0.75(1 - x^2)I\{ x \leq 1\}$
'normal'	Gaussian	$f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2)$

Value	Kernel	Formula
'triangle'	Triangular	$f(x) = (1 - x)I\{ x \leq 1\}$

If you specify a 1-by- P cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel smoother type in cell j for feature j in X . The software ignores cells of `Kernel` not corresponding to a predictor whose distribution is '`kernel`'.

You must specify that at least one predictor has distribution '`kernel`' to additionally specify `Kernel`, `Support`, or `Width`.

Example: '`Kernel`', {'epanechnikov', 'normal'}

Data Types: cell | char

'Support' — Kernel smoothing density support

'unbounded' (default) | 'positive' | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of '`Support`' and '`positive`', '`unbounded`', a cell array, or a numeric row vector. The software applies the kernel smoothing density to the specified region.

This table summarizes the available options for setting the kernel smoothing density region.

Value	Description
1-by-2 numeric row vector	For example, $[L, U]$, where L and U are the finite lower and upper bounds, respectively, for the density support.
'positive'	The density support is all positive real values.
'unbounded'	The density support is all real values.

If you specify a 1-by- P cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel support in cell j for feature j in X . The software ignores cells of `Kernel` not corresponding to a predictor whose distribution is '`kernel`'.

You must specify that at least one predictor has distribution '`kernel`' to additionally specify `Kernel`, `Support`, or `Width`.

Example: '`KSSupport`', {[-10,20], 'unbounded'}

Data Types: `cell` | `char` | `double`

'Width' — Kernel smoothing window width

matrix of numeric values | numeric column vector | numeric row vector | scalar

Kernel smoothing window width, specified as the comma-separated pair consisting of 'Width' and a matrix of numeric values, numeric column vector, numeric row vector, or scalar.

Suppose there are K class levels and P predictors. This table summarizes the available options for setting the kernel smoothing window width.

Value	Description
K -by- P matrix of numeric values	Element (k,j) specifies the width for predictor j in class k .
K -by-1 numeric column vector	Element k specifies the width for all predictors in class k .
1-by- P numeric row vector	Element j specifies the width in all class levels for predictor j .
scalar	Specifies the bandwidth for all features in all classes.

By default, the software selects a default width automatically for each combination of predictor and class by using a value that is optimal for a Gaussian distribution. If you specify `Width` and it contains NaNs, then the software selects widths for the elements containing NaNs.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: 'Width', [NaN NaN]

Data Types: `double` | `struct`

Cross-Validation Options

'CrossVal' — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: 'CrossVal', 'on'

'CVPartition' — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Holdout', 0.1

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'KFold', 5

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations, where n is `size(Mdl.X, 1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Leaveout', 'on'

Data Types: `char`

Other Classification Options

'CategoricalPredictors' — Categorical predictors list

numeric vector | logical vector | cell array of character vectors | character array | 'all' | []

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- A numeric vector with indices from 1 through `p`, where `p` is the number of columns of `X`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X` is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

By default, if the predictor data is in a matrix (`X`), `fitcnb` assumes that none of the predictors are categorical. If the predictor data is in a table (`Tbl`), `fitcnb` assumes that a variable is categorical if it contains logical values, categorical values, or a cell array of character vectors.

Example: 'CategoricalPredictors', 'all'

Data Types: single | double | char | cell

'ClassNames' — Names of classes to use for training

categorical array | cell array of character vectors | character array | logical vector | numeric vector

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` must be the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.

- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is $\{ 'a', 'b', 'c' \}$. To train the model using observations from classes 'a' and 'c' only, specify `'ClassNames', {'a', 'c'}`.

The default is the set of all distinct class names in Y .

Example: `'ClassNames', {'b', 'g'}`

Data Types: `categorical | char | logical | single | double | cell`

'Cost' — Cost of misclassification

`square matrix | structure`

Cost of misclassification of a point, specified as the comma-separated pair consisting of `'Cost'` and one of the following:

- Square matrix, where `Cost(i, j)` is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as Y , and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if $i \neq j$, and `Cost(i, j)=0` if $i=j$.

Example: `'Cost', struct('ClassNames', {'b', 'g'}, 'ClassificationCosts', [0 0.5; 1 0])`

Data Types: `single | double | struct`

'PredictorNames' — Predictor variable names

`cell array of unique character vectors`

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply X and Y , then you can use `'PredictorNames'` to give the predictor variables in X names.
 - The order of the names in `PredictorNames` must correspond to the column order of X . That is, `PredictorNames{1}` is the name of $X(:, 1)$,

`PredictorNames{2}` is the name of $X(:,2)$, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.

- By default, `PredictorNames` is `{x1,x2,...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitcnb` uses the predictor variables in `PredictorNames` and the response only in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It good practice to specify the predictors for training using one of `'PredictorNames'` or `formula` only.

Example: `'PredictorNames'`,
`{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `cell`

'Prior' — Prior probabilities

`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
<code>'empirical'</code>	The class prior probabilities are the class relative frequencies in Y .
<code>'uniform'</code>	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	A structure <code>S</code> with two fields:

Value	Description
	<ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior', 'uniform'`

Data Types: `single` | `double` | `struct`

'ResponseName' — Response variable name

`'Y'` (default) | character vector

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName', 'response'`

Data Types: `char`

'ScoreTransform' — Score transform function

`'none'` (default) | character vector | function handle

Score transform function, specified as the comma-separated pair consisting of `'ScoreTransform'` and a function handle or value in this table.

Value	Formula
<code>'doublelogit'</code>	$1/(1 + e^{-2x})$
<code>'invlogit'</code>	$\log(x / (1-x))$
<code>'ismax'</code>	Set the score for the class with the largest score to 1, and scores for all other classes to 0.

Value	Formula
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: function_handle | char

'Weights' — Observation weights

numeric vector of positive values | character vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as 'W'. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n, 1)`, where n is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char`

Hyperparameter Optimization

'OptimizeHyperparameters' — Parameters to optimize

'none' (default) | 'auto' | 'all' | cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as:

- 'none' — Do not optimize.
- 'auto' — Use {'DistributionNames', 'Width'}
- 'all' — Optimize all eligible parameters.
- Cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitcnb` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 29-3219. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note: `OptimizeHyperparameters` values override any values you set using other name-value pairs. For example, setting `OptimizeHyperparameters` to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitcnb` are:

- `DistributionNames` — `fitcnb` searches among 'normal' and 'kernel'.
- `Width` — `fitcnb` searches among real values, by default log-scaled in the range `[MinPredictorDiff/4, max(MaxPredictorRange, MinPredictorDiff)]`.
- `Kernel` — `fitcnb` searches among 'normal', 'box', 'epanechnikov', and 'triangle'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
```

```
params = hyperparameters('fitcnb',meas,species);
params(2).Range = [1e-2,1e2];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression, and the misclassification rate for classification. To control the iterative display, set the `HyperparameterOptimizationOptions` name-value pair, `Verbose` field. To control the plots, set the `HyperparameterOptimizationOptions` name-value pair, `ShowPlots` field.

For an example, see “Optimize Naive Bayes Classifier” on page 29-2038.

Example: 'auto'

Data Types: char | cell

'HyperparameterOptimizationOptions' — Options for optimization structure

Options for optimization, specified as a structure. Modifies the effect of the `OptimizeHyperparameters` name-value pair. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the <code>commandsortrows(Mdl.ParameterOptim</code></p>	'bayesopt'

Field Name	Values	Default
AcquisitionFunc	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>For details, see the <code>bayesopt</code> AcquisitionFunctionName name-value pair, or “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEva	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
NumGridDivision	For 'gridsearch', the number of values in each dimension. Can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. Ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , plots the best objective function value against iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is 'bayesopt', then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>

Field Name	Values	Default
SaveIntermediate	Logical value indicating whether to save results when <code>Optimizer</code> is 'bayesopt'. If <code>true</code> , overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a <code>BayesianOptimization</code> object.	false
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesoptVerbose</code> name-value pair.	1
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <p><code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.</p>	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code>	Kfold = 5
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example: `struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

Mdl — Trained naive Bayes classification model

`ClassificationNaiveBayes` model object | `ClassificationPartitionedModel`
cross-validated model object

Trained naive Bayes classification model, returned as a `ClassificationNaiveBayes` model object or a `ClassificationPartitionedModel` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedModel` cross-validated model object. Otherwise, `Mdl` is a `ClassificationNaiveBayes` model object.

To reference properties of `Mdl`, use dot notation. For example, to access the estimated distribution parameters, enter `Mdl.DistributionParameters`.

Definitions

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor j is the nonnegative number of occurrences of token j in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].

Naive Bayes classifiers assign observations to the most probable class (in other words, the *maximum a posteriori* decision rule). Explicitly, the algorithm:

- 1 Estimates the densities of the predictors within each class.
- 2 Models posterior probabilities according to Bayes rule. That is, for all $k = 1, \dots, K$,

$$\hat{P}(Y = k | X_1, \dots, X_P) = \frac{\pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)}{\sum_{k=1}^K \pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)},$$

where:

- Y is the random variable corresponding to the class index of an observation.
 - X_1, \dots, X_P are the random predictors of an observation.
 - $\pi(Y = k)$ is the prior probability that a class index is k .
- 3** Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior

probability $\hat{P}(Y = k | X_1, \dots, X_P) \propto \pi(Y = k) P_{mn}(X_1, \dots, X_P | Y = k)$, where

$P_{mn}(X_1, \dots, X_P | Y = k)$ is the probability mass function of a multinomial distribution.

Tips

For classifying count-based data, such as the bag-of-tokens model, use the multinomial distribution (e.g., set 'Distribution', 'mn').

Algorithms

- If you specify 'Distribution', 'mn' when training Mdl using fitcnb, then the software fits a multinomial distribution using the bag-of-tokens model on page 29-2060. The software stores the probability that token j appears in class k in the property `DistributionParameters{k,j}`. Using additive smoothing [2], the estimated probability is

$$P(\text{token } j | \text{class } k) = \frac{1 + c_{jk}}{P + c_k},$$

where:

- $$c_{j|k} = n_k \frac{\sum_{i: y_i \in \text{class } k} x_{ij} w_i}{\sum_{i: y_i \in \text{class } k} w_i};$$
 which is the weighted number of occurrences of token j in

class k .

- n_k is the number of observations in class k .
- w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
- $$c_k = \sum_{j=1}^P c_{j|k};$$
 which is the total weighted number of occurrences of all tokens in class k .

- If you specify 'Distribution', 'mvnm' when training Mdl using `fitcnb`, then:
 - 1 For each predictor, the software collects a list of the unique levels, stores the sorted list in `CategoricalLevels`, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.
 - 2 For predictor j in class k , the software counts instances of each categorical level using the list stored in `CategoricalLevels{j}`.
 - 3 The software stores the probability that predictor j , in class k , has level L in the property `DistributionParameters{k,j}`, for all levels in `CategoricalLevels{j}`. Using additive smoothing [2], the estimated probability is

$$P(\text{predictor } j = L \mid \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},$$

where:

- $$m_{j|k}(L) = n_k \frac{\sum_{i: y_i \in \text{class } k} I\{x_{ij} = L\} w_i}{\sum_{i: y_i \in \text{class } k} w_i};$$
 which is the weighted number of

observations for which predictor j equals L in class k .

- n_k is the number of observations in class k .
- $I\{x_{ij} = L\} = 1$ if $x_{ij} = L$, 0 otherwise.
- w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
- m_j is the number of distinct levels in predictor j .
- m_k is the weighted number of observations in class k .

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Tall Arrays

This function supports tall arrays for out-of-memory data with the limitations:

- Supported syntaxes are:

- `discr = fitcnb(Tbl,Y)`
- `discr = fitcnb(X,Y)`
- `discr = fitcnb(___,Name,Value)`
- Options related to kernel densities, cross-validation, and hyperparameter optimization are not supported. The supported name-value pairs are:
 - `'DistributionNames'` — `'kernel'` value is not supported.
 - `'CategoricalPredictors'`
 - `'PredictorNames'`
 - `'ResponseName'`
 - `'ScoreTransform'`
 - `'Weights'` — Value must be a tall array.

For more information, see “Tall Arrays” (MATLAB).

Topics

“Naive Bayes Classification” on page 17-38

“Grouping Variables” on page 2-58

Introduced in R2014b

fitcsvm

Train binary support vector machine classifier

`fitcsvm` trains or cross-validates a support vector machine (SVM) model for two-class (binary) classification on a low- through moderate-dimensional predictor data set. `fitcsvm` supports mapping the predictor data using kernel functions, and supports SMO, ISDA, or $L1$ soft-margin minimization via quadratic programming for objective-function minimization.

To train a linear SVM model for binary classification on a high-dimensional data set, that is, data sets that include many predictor variables, use `fitclinear` instead.

For multiclass learning by combining binary SVM models, use error-correcting output codes (ECOC). For more details, see `fitcecoc`.

To train an SVM regression model, see `fitrsvm` for low- through moderate-dimensional predictor data sets, or `fitrlinear` for high-dimensional data sets.

Syntax

```
Mdl = fitcsvm(Tbl,ResponseVarName)
```

```
Mdl = fitcsvm(Tbl,formula)
```

```
Mdl = fitcsvm(Tbl,Y)
```

```
Mdl = fitcsvm(X,Y)
```

```
Mdl = fitcsvm(___,Name,Value)
```

Description

`Mdl = fitcsvm(Tbl,ResponseVarName)` returns a support vector machine classifier `Mdl` trained using the sample data contained in a table (`Tbl`). `ResponseVarName` is the name of the variable in `Tbl` that contains the class labels for one- or two-class classification.

`Mdl = fitcsvm(Tbl,formula)` returns an SVM classifier trained using the sample data contained in a table (`Tbl`). `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitcsvm(Tbl,Y)` returns an SVM classifier trained using the predictor variables in table `Tbl` and class labels in vector `Y`.

`Mdl = fitcsvm(X,Y)` returns an SVM classifier trained using the predictors in the matrix `X` and class labels in vector `Y` for one- or two-class classification.

`Mdl = fitcsvm(___,Name,Value)` returns a support vector machine classifier with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify the type of cross-validation, the cost for misclassification, or the type of score transformation function.

Examples

Train a Support Vector Machine Classifier

Load Fisher's iris data set. Remove the sepal lengths and widths, and all observed setosa irises.

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,3:4);
y = species(inds);
```

Train an SVM classifier using the processed data set.

```
SVModel = fitcsvm(X,y)
```

```
SVModel =
```

```
ClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
           ClassNames: {'versicolor' 'virginica'}
    ScoreTransform: 'none'
    NumObservations: 100
           Alpha: [24×1 double]
           Bias: -14.4149
    KernelParameters: [1×1 struct]
           BoxConstraints: [100×1 double]
           ConvergenceInfo: [1×1 struct]
```

```
IsSupportVector: [100x1 logical]
Solver: 'SMO'
```

The Command Window shows that `SVMMModel` is a trained `ClassificationSVM` classifier and a property list. Display the properties of `SVMMModel`, for example, to determine the class order, by using dot notation.

```
classOrder = SVMMModel.ClassNames
```

```
classOrder =
    2x1 cell array
    'versicolor'
    'virginica'
```

The first class ('`versicolor`') is the negative class, and the second ('`virginica`') is the positive class. You can change the class order during training by using the '`ClassNames`' name-value pair argument.

Plot a scatter diagram of the data and circle the support vectors.

```
sv = SVMMModel.SupportVectors;
figure
gscatter(X(:,1),X(:,2),y)
hold on
plot(sv(:,1),sv(:,2),'ko','MarkerSize',10)
legend('versicolor','virginica','Support Vector')
hold off
```

The support vectors are observations that occur on or beyond their estimated class boundaries.

You can adjust the boundaries (and therefore the number of support vectors) by setting a box constraint during training using the 'BoxConstraint' name-value pair argument.

Train and Cross Validate an SVM Classifier

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier using the radial basis kernel. Let the software find a scale value for the kernel function. It is good practice to standardize the predictors.

```
SVMMModel = fitcsvm(X,Y,'Standardize',true,'KernelFunction','RBF',...
    'KernelScale','auto');
```

SVMMModel is a trained `ClassificationSVM` classifier.

Cross validate the SVM classifier. By default, the software uses 10-fold cross validation.

```
CVSVMMModel = crossval(SVMMModel);
```

CVSVMMModel is a `ClassificationPartitionedModel` cross-validated classifier.

Estimate the out-of-sample misclassification rate.

```
classLoss = kfoldLoss(CVSVMMModel)
```

```
classLoss =
```

```
    0.0484
```

The generalization rate is approximately 5%.

Detect Outliers Using SVM and One-Class Learning

Load Fisher's iris data set. Remove the petal lengths and widths. Treat all irises as coming from the same class.

```
load fisheriris
X = meas(:,1:2);
y = ones(size(X,1),1);
```

Train an SVM classifier using the processed data set. Assume that 5% of the observations are outliers. It is good practice to standardize the predictors.

```
rng(1);
SVMMModel = fitcsvm(X,y,'KernelScale','auto','Standardize',true,...
    'OutlierFraction',0.05);
```

SVMMModel is a trained `ClassificationSVM` classifier. By default, the software uses the Gaussian kernel for one-class learning.

Plot the observations and the decision boundary. Flag the support vectors and potential outliers.

```
svInd = SVMModel.IsSupportVector;
h = 0.02; % Mesh grid step size
[X1,X2] = meshgrid(min(X(:,1)):h:max(X(:,1)),...
    min(X(:,2)):h:max(X(:,2)));
[~,score] = predict(SVMModel,[X1(:),X2(:)]);
scoreGrid = reshape(score,size(X1,1),size(X2,2));

figure
plot(X(:,1),X(:,2),'k.')
hold on
plot(X(svInd,1),X(svInd,2),'ro','MarkerSize',10)
contour(X1,X2,scoreGrid)
colorbar;
title('{\bf Iris Outlier Detection via One-Class SVM}')
xlabel('Sepal Length (cm)')
ylabel('Sepal Width (cm)')
legend('Observation','Support Vector')
hold off
```

The boundary separating the outliers from the rest of the data occurs where the contour value is 0.

Verify that the fraction of observations with negative scores in the cross-validated data is close to 5%.

```
CVSVMModel = crossval(SVMModel);
[~,scorePred] = kfoldPredict(CVSVMModel);
outlierRate = mean(scorePred<0)
```

```
outlierRate =
```

```
0.0467
```

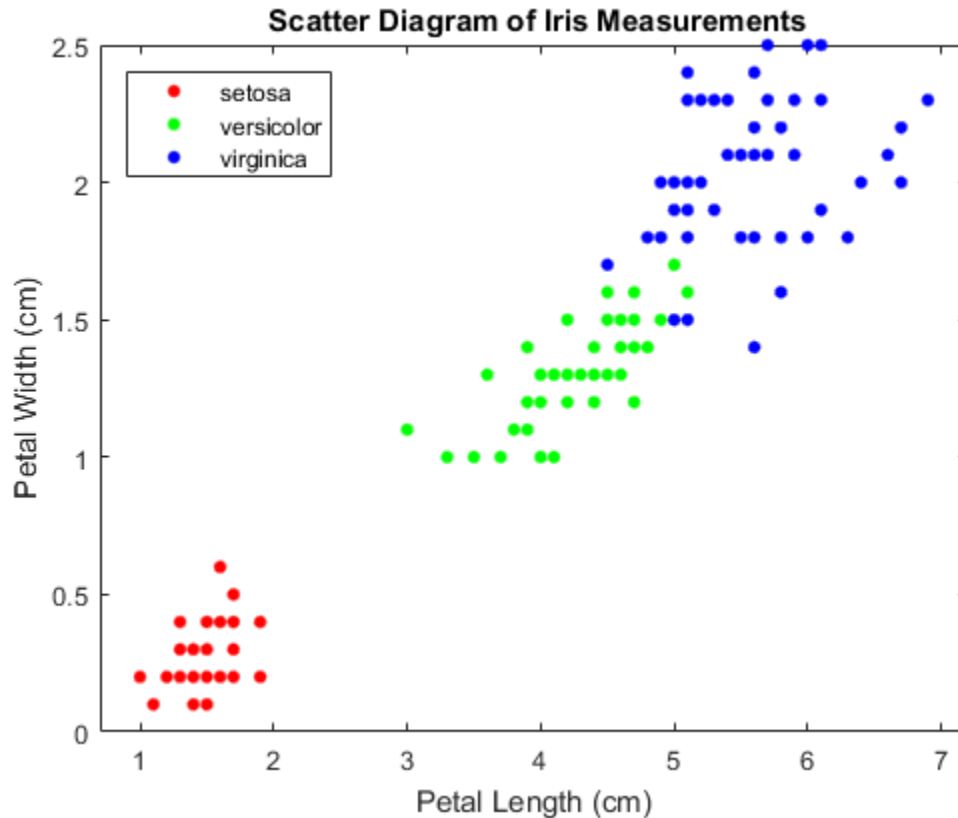

Find Multiple Class Boundaries Using Binary SVM

Load Fisher's iris data set. Use the petal lengths and widths.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Examine a scatter plot of the data.

```
figure
gscatter(X(:,1),X(:,2),Y);
h = gca;
lims = [h.XLim h.YLim]; % Extract the x and y axis limits
title('\bf Scatter Diagram of Iris Measurements');
xlabel('Petal Length (cm)');
ylabel('Petal Width (cm)');
legend('Location', 'Northwest');
```

There are three classes, one of which is linearly separable from the others.

For each class:

- 1 Create a logical vector (`indx`) indicating whether an observation is a member of the class.
- 2 Train an SVM classifier using the predictor data and `indx`.
- 3 Store the classifier in a cell of a cell array.

It is good practice to define the class order.

```
SVMModels = cell(3,1);
classes = unique(Y);
```

```

rng(1); % For reproducibility

for j = 1:numel(classes);
    indx = strcmp(Y,classes(j)); % Create binary classes for each classifier
    SVMModels{j} = fitcsvm(X,indx,'ClassNames',[false true],'Standardize',true,...
        'KernelFunction','rbf','BoxConstraint',1);
end

```

`SVMModels` is a 3-by-1 cell array, with each cell containing a `ClassificationSVM` classifier. For each cell, the positive class is *setosa*, *versicolor*, and *virginica*, respectively.

Define a fine grid within the plot, and treat the coordinates as new observations from the distribution of the training data. Estimate the score of the new observations using each classifier.

```

d = 0.02;
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...
    min(X(:,2)):d:max(X(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];
N = size(xGrid,1);
Scores = zeros(N,numel(classes));

for j = 1:numel(classes);
    [~,score] = predict(SVMModels{j},xGrid);
    Scores(:,j) = score(:,2); % Second column contains positive-class scores
end

```

Each row of `Scores` contains three scores. The index of the element with the largest score is the index of the class to which the new class observation most likely belongs.

Associate each new observation with the classifier that gives it the maximum score.

```
[~,maxScore] = max(Scores,[],2);
```

Color in the regions of the plot based on which class the corresponding new observation belongs.

```

figure
h(1:3) = gscatter(xGrid(:,1),xGrid(:,2),maxScore,...

Optimize SVM Classifier

This example shows how to optimize hyperparameters automatically using `fitcsvm`. The example uses the `ionosphere` data.

Load the data.

```
load ionosphere
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng default
Mdl = fitcsvm(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
    'expected-improvement-plus'))
```

Iter	Eval result	Objective	Objective runtime	BestSoFar (observed)	BestSoFar (estim.)	BoxConstraint

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

Data Types: table

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element must correspond to one row of the array.

It is good practice to specify the order of the classes using the `ClassNames` name-value pair argument.

Data Types: char

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of 'Y~X1+X2+X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables. The variables must be variable names in Tbl (Tbl.Properties.VariableNames).

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

Data Types: char

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels to which the SVM model is trained, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

- Y must contain at most two distinct classes. For multiclass learning, see `fitcecoc`.
- If Y is a character array, then each element must correspond to one row of the array.
- The length of Y and the number of rows of Tbl or X must be equal.
- It is good practice to specify the class order using the `ClassNames` name-value pair argument.

Data Types: char | cell | categorical | logical | single | double

X — Predictor data

matrix of numeric values

Predictor data to which the SVM classifier is trained, specified as a matrix of numeric values.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one predictor.

The length of Y and the number of rows of X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the `PredictorNames` name-value pair argument.

Data Types: double | single

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Note: You cannot use any cross-validation name-value pair along with `OptimizeHyperparameters`. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair.

Example: `'Kfold', 10, 'Cost', [0 2; 1 0], 'ScoreTransform', 'sign'` specifies to perform 10-fold cross-validation, apply double the penalty to false positives compared to false negatives, and transform the scores using the sign function.

Support Vector Machine Options

'BoxConstraint' — Box constraint

1 (default) | positive scalar

Box constraint, specified as the comma-separated pair consisting of `'BoxConstraint'` and a positive scalar.

For one-class learning, the software always sets the box constraint to 1.

For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see “Algorithms” on page 29-2109.

Example: `'BoxConstraint', 100`

Data Types: `double` | `single`

'KernelFunction' — Kernel function

'linear' (default) | 'gaussian' | 'rbf' | 'polynomial' | function name

Kernel function used to compute the Gram matrix, specified as the comma-separated pair consisting of `'KernelFunction'` and a value in this table.

Value	Description	Formula
'gaussian' or 'rbf'	Gaussian or Radial Basis Function (RBF) kernel, default for one-class learning	$G(x_1, x_2) = \exp\left(-\ x_1 - x_2\ ^2\right)$
'linear'	Linear kernel, default for two-class learning	$G(x_1, x_2) = x_1'x_2$
'polynomial'	Polynomial kernel. Use 'PolynomialOrder', p to specify a polynomial kernel of order p .	$G(x_1, x_2) = (1 + x_1'x_2)^p$

You can set your own kernel function, for example, `kernel`, by setting 'KernelFunction', 'kernel'. `kernel` must have the following form:

```
function G = kernel(U,V)
```

where:

- U is an m -by- p matrix.
- V is an n -by- p matrix.
- G is an m -by- n Gram matrix of the rows of U and V .

And `kernel.m` must be on the MATLAB path.

It is good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function 'mysigmoid' rather than 'sigmoid'.

Example: 'KernelFunction', 'gaussian'

Data Types: char

'KernelScale' — Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software divides all elements of the predictor matrix X by the value of `KernelScale`. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

- If you specify 'auto', then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary

from one call to another. Therefore, to reproduce results, set a random number seed using `rng` before training.

- If you specify `KernelScale` and your own kernel function, for example, `kernel`, using `'KernelFunction'`, `'kernel'`, then the software throws an error. You must apply scaling within `kernel`.

Example: `'KernelScale','auto'`

Data Types: `double` | `single` | `char`

'PolynomialOrder' — Polynomial kernel function order

3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of `'PolynomialOrder'` and a positive integer.

If you set `'PolynomialOrder'` and `KernelFunction` is not `'polynomial'`, then the software throws an error.

Example: `'PolynomialOrder',2`

Data Types: `double` | `single`

'KernelOffset' — Kernel offset parameter

nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of `'KernelOffset'` and a nonnegative scalar.

The software adds `KernelOffset` to each element of the Gram matrix.

The defaults are:

- 0 if the solver is SMO (that is, you set `'Solver','SMO'`)
- 0.1 if the solver is ISDA (that is, you set `'Solver','ISDA'`)

Example: `'KernelOffset',0`

Data Types: `double` | `single`

'Standardize' — Flag to standardize predictor data

false (default) | true

Flag to standardize the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and true (1) or false (0).

If you set `'Standardize', true`:

- The software centers and scales each column of the predictor data (X) by the weighted column mean and standard deviation, respectively (for details on weighted standardizing, see “Algorithms” on page 29-2109). MATLAB does not standardize the data contained in the dummy variable columns generated for categorical predictors.
- The software trains the classifier using the standardized predictor matrix, but stores the unstandardized data in the classifier property X.

Example: `'Standardize', true`

Data Types: `logical`

'Solver' — Optimization routine

`'ISDA' | 'L1QP' | 'SMO'`

Optimization routine, specified as the comma-separated pair consisting of `'Solver'` and a value in this table.

Value	Description
<code>'ISDA'</code>	Iterative Single Data Algorithm (see [30])
<code>'L1QP'</code>	Uses <code>quadprog</code> to implement <i>L1</i> soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license. For more details, see “Quadratic Programming Definition” (Optimization Toolbox).
<code>'SMO'</code>	Sequential Minimal Optimization (see [17])

The defaults are:

- `'ISDA'` if you set `'OutlierFraction'` to a positive value and for two-class learning
- `'SMO'` otherwise

Example: `'Solver', 'ISDA'`

Data Types: `char`

'Alpha' — Initial estimates of alpha coefficients

numeric vector of nonnegative values

Initial estimates of alpha coefficients, specified as the comma-separated pair consisting of 'Alpha' and a numeric vector of nonnegative values. The length of Alpha must be equal to the number of rows of X.

- Each element of Alpha corresponds to an observation in X.
- Alpha cannot contain any NaNs.
- If you specify Alpha and any one of the cross-validations name-value pair arguments ('CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'), then the software returns an error.

If Y contains any missing values, then remove all rows of Y, X, and Alpha that correspond to the missing values. That is, enter:

```
idx = ~isundefined(categorical(Y));  
Y = Y(idx,:);  
X = X(idx,:);  
alpha = alpha(idx);
```

Then, pass Y, X, and alpha as the response, predictors, and initial alpha estimates, respectively.

The defaults are:

- `0.5*ones(size(X,1),1)` for one-class learning
- `zeros(size(X,1),1)` for two-class learning

Example: 'Alpha',`0.1*ones(size(X,1),1)`

Data Types: double | single

'CacheSize' — Cache size

1000 (default) | 'maximal' | positive scalar

Cache size, specified as the comma-separated pair consisting of 'CacheSize' and 'maximal' or a positive scalar.

If CacheSize is 'maximal', then the software reserves enough memory to hold the entire n -by- n Gram matrix.

If CacheSize is a positive scalar, then the software reserves CacheSize megabytes of memory for training the model.

Example: 'CacheSize', 'maximal'

Data Types: double | char | single

'ClipAlphas' — Flag to clip alpha coefficients

true (default) | false

Flag to clip alpha coefficients, specified as the comma-separated pair consisting of 'ClipAlphas' and either true or false.

Suppose that the alpha coefficient for observation j is α_j and the box constraint of observation j is C_j , $j = 1, \dots, n$. n is the training sample size.

Value	Description
true	At each iteration, if α_j is near 0 or near C_j , then MATLAB sets α_j to 0 or to C_j , respectively.
false	MATLAB does not change the alpha coefficients during optimization.

MATLAB stores the final values of α in the Alpha property of the trained SVM model object.

ClipAlphas can affect SMO and ISDA convergence.

Example: 'ClipAlphas', false

Data Types: logical

'Nu' — ν parameter for one-class learning

0.5 (default) | positive scalar

ν parameter for one-class learning, specified as the comma-separated pair consisting of 'Nu' and a positive scalar. Nu must be greater than 0 and at most 1.

Set Nu to control the tradeoff between ensuring most training examples are in the positive class and minimizing the weights in the score function.

Example: 'Nu', 0.25

Data Types: double | single

'NumPrint' — Number of iterations between optimization diagnostic message output

1000 (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of 'NumPrint' and a nonnegative integer.

If you use `'Verbose', 1` and `'NumPrint', numprint`, then the software displays all optimization diagnostic messages from SMO and ISDA every `numprint` iterations in the Command Window.

Example: `'NumPrint', 500`

Data Types: `double` | `single`

'OutlierFraction' — Expected proportion of outliers in training data

0 (default) | numeric scalar in the interval [0,1)

Expected proportion of outliers in the training data, specified as the comma-separated pair consisting of `'OutlierFraction'` and a numeric scalar in the interval [0,1).

If you set `'OutlierFraction', outlierfraction`, where `outlierfraction` is a value greater than 0, then:

- For two-class learning, the software implements *robust learning*. In other words, the software attempts to remove $100 \times \text{outlierfraction}\%$ of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- For one-class learning, the software finds an appropriate bias term such that `outlierfraction` of the observations in the training set have negative scores.

Example: `'OutlierFraction', 0.01`

Data Types: `double` | `single`

'RemoveDuplicates' — Flag to replace duplicate observations with single observations in training data

false (default) | true

Flag to replace duplicate observations with single observations in the training data, specified as the comma-separated pair consisting of `'RemoveDuplicates'` and `true` or `false`.

If `RemoveDuplicates` is `true`, then `fitcsvm` replaces duplicate observations in the training data with a single observation of the same value. The weight of the single observation is equal to the sum of the weights of the corresponding removed duplicates (see `Weights`).

Tip: If your data set contains many duplicate observations, then specifying `'RemoveDuplicates', true` can decrease convergence time considerably.

Data Types: logical

'Verbose' – Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either 0, 1, or 2. `Verbose` controls the amount of optimization information that the software displays in the Command Window and saves as a structure to `Mdl.ConvergenceInfo.History`.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display or save convergence information.
1	The software displays diagnostic messages and saves convergence criteria every <code>numprint</code> iterations, where <code>numprint</code> is the value of the name-value pair argument 'NumPrint'.
2	The software displays diagnostic messages and saves convergence criteria at every iteration.

Example: 'Verbose',1

Data Types: double | single

Other Classification Options

'CategoricalPredictors' – Categorical predictors list

numeric or logical vector | cell array of character vectors | 'all'

List of categorical predictors, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- A numeric vector with indices from 1 through `p`, where `p` is the number of columns of `X`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X` is a categorical variable.

- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- `'all'`, meaning all predictors are categorical.

By default, if the predictor data is in a matrix (`X`), `fitcsvm` assumes that none of the predictors are categorical. If the predictor data is in a table (`Tbl`), `fitcsvm` assumes that a variable is categorical if it contains logical values, categorical values, or a cell array of character vectors.

For example, the following syntax specifies that columns 1 and 3 of the input matrix `X` contain categorical variables.

Example: `'CategoricalPredictors',[1,3]`

Data Types: `single` | `double` | `logical` | `cell`

'ClassNames' — Names of classes to use for training

categorical array | cell array of character vectors | character array | logical vector | numeric vector

Names of classes to use for training, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` must be the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default is the set of all distinct class names in `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

'Cost' — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of **'Cost'** and a square matrix or structure. If you specify:

- The square matrix **Cost**, then, if true class of an observation is *i*, **Cost(i, j)** is the cost of classifying a point into class *j*. That is, rows correspond to the true classes and the columns correspond to predicted classes. To specify the class order for the corresponding rows and columns of **Cost**, also specify the **ClassNames** name-value pair argument.
- The structure **S**, then it must have two fields:
 - **S.ClassNames**, which contains the class names as a variable of the same data type as **Y**
 - **S.ClassificationCosts**, which contains the cost matrix with rows and columns ordered as in **S.ClassNames**

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix. Consequently, the cost matrix resets to the default. For more details on the relationships and algorithmic behavior of **BoxConstraint**, **Cost**, **Prior**, **Standardize**, and **Weights**, see “Algorithms” on page 29-2109.

The defaults are:

- For one-class learning, **Cost** = 0.
- For two-class learning, **Cost(i, j)** = 1 if $i \neq j$, and **Cost(i, j)** = 0 if $i = j$.

Example: **'Cost'**, [0,1;2,0]

Data Types: double | single | struct

'PredictorNames' — Predictor variable names

cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of **'PredictorNames'** and a cell array of unique character vectors. The functionality of **'PredictorNames'** depends on the way you supply the training data.

- If you supply **X** and **Y**, then you can use **'PredictorNames'** to give the predictor variables in **X** names.

- The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
- By default, `PredictorNames` is `{x1,x2,...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitcsvm` uses the predictor variables in `PredictorNames` and the response only in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It good practice to specify the predictors for training using one of `'PredictorNames'` or `formula` only.

Example: `'PredictorNames'`,
`{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `cell`

'Prior' — Prior probabilities

`'empirical'` (default) | `'uniform'` | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
<code>'empirical'</code>	The class prior probabilities are the class relative frequencies in <code>Y</code> .
<code>'uniform'</code>	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	A structure <code>S</code> with two fields:

Value	Description
	<ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix. For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see “Algorithms” on page 29-2109.

Example: `struct('ClassNames',
{'setosa','versicolor','virginica'}),'ClassProbs',1:3)`

Data Types: `char` | `double` | `single` | `struct`

'ResponseName' — Response variable name

'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector.

- If you supply `Y`, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use 'ResponseName'.

Example: `'ResponseName','response'`

Data Types: `char`

'ScoreTransform' — Score transform function

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'sign' | 'symmetric' | 'symmetriclogit' | 'symmetricismax' | function handle

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector or function handle.

- This table summarizes the available built-in functions.

Value	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

`function` must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'sign'

Data Types: char | function_handle

'Weights' — Observation weights

numeric vector | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a

character vector. For example, if the weights vector W is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including W , as predictors or the response when training the model.

By default, `Weights` is `ones(n, 1)`, where n is the number of observations in X or `Tbl`.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class. For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see “Algorithms” on page 29-2109.

Data Types: `double` | `single`

Cross-Validation Options

'CrossVal' — Flag to train cross-validated classifier

`'off'` (default) | `'on'`

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using one of the `CVPartition`, `Holdout`, `KFold`, or `Leaveout` name-value pair arguments. You can only use one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: `'Crossval', 'on'`

Data Types: `char`

'CVPartition' — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold', 5`

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations, where n is `size(Mdl.X,1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Leaveout', 'on'

Data Types: char

Convergence Controls

'DeltaGradientTolerance' — Tolerance for gradient difference

nonnegative scalar

Tolerance for the gradient difference between upper and lower violators obtained by Sequential Minimal Optimization (SMO) or Iterative Single Data Algorithm (ISDA), specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar.

If `DeltaGradientTolerance` is 0, then the software does not use the tolerance for the gradient difference to check for optimization convergence.

The defaults are:

- `1e-3` if the solver is SMO (for example, you set 'Solver', 'SMO')
- `0` if the solver is ISDA (for example, you set 'Solver', 'ISDA')

Example: 'DeltaGapTolerance', `1e-2`

Data Types: double | single

'GapTolerance' — Feasibility gap tolerance

0 (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'GapTolerance' and a nonnegative scalar.

If `GapTolerance` is 0, then the software does not use the feasibility gap tolerance to check for optimization convergence.

Example: `'GapTolerance', 1e-2`

Data Types: `double` | `single`

'IterationLimit' — Maximal number of numerical optimization iterations

`1e6` (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

The software returns a trained model regardless of whether the optimization routine successfully converges. `Mdl.ConvergenceInfo` contains convergence information.

Example: `'IterationLimit', 1e8`

Data Types: `double` | `single`

'KKTolerance' — Karush-Kuhn-Tucker complementarity conditions violation tolerance

nonnegative scalar

Karush-Kuhn-Tucker (KKT) complementarity conditions violation tolerance, specified as the comma-separated pair consisting of `'KKTolerance'` and a nonnegative scalar.

If `KKTolerance` is 0, then the software does not use the KKT complementarity conditions violation tolerance to check for optimization convergence.

The defaults are:

- 0 if the solver is SMO (for example, you set `'Solver', 'SMO'`)
- `1e-3` if the solver is ISDA (for example, you set `'Solver', 'ISDA'`)

Example: `'KKTolerance', 1e-2`

Data Types: `double` | `single`

'ShrinkagePeriod' — Number of iterations between movement of observations from active to inactive set

0 (default) | nonnegative integer

Number of iterations between the movement of observations from the active to inactive set, specified as the comma-separated pair consisting of `'ShrinkagePeriod'` and a nonnegative integer.

If you set `'ShrinkagePeriod',0`, then the software does not shrink the active set.

Example: `'ShrinkagePeriod',1000`

Data Types: `double` | `single`

Hyperparameter Optimization

'OptimizeHyperparameters' — Parameters to optimize

'none' (default) | 'auto' | 'all' | cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as:

- 'none' — Do not optimize.
- 'auto' — Use {'BoxConstraint', 'KernelScale'}
- 'all' — Optimize all eligible parameters.
- Cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitcsvm` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 29-3219. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note: `OptimizeHyperparameters` values override any values you set using other name-value pairs. For example, setting `OptimizeHyperparameters` to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitcsvm` are:

- `BoxConstraint` — `fitcsvm` searches among positive values, by default log-scaled in the range `[1e-3,1e3]`.
- `KernelScale` — `fitcsvm` searches among positive values, by default log-scaled in the range `[1e-3,1e3]`.
- `KernelFunction` — `fitcsvm` searches among 'gaussian', 'linear', and 'polynomial'.

- `PolynomialOrder` — `fitcsvm` searches among integers in the range `[2,4]`.
- `Standardize` — `fitcsvm` searches among `'true'` and `'false'`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcsvm',meas,species);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression, and the misclassification rate for classification. To control the iterative display, set the `HyperparameterOptimizationOptions` name-value pair, `Verbose` field. To control the plots, set the `HyperparameterOptimizationOptions` name-value pair, `ShowPlots` field.

For an example, see “Optimize SVM Classifier” on page 29-2075.

Example: `'auto'`

Data Types: `char` | `cell`

'HyperparameterOptimizationOptions' — Options for optimization

structure

Options for optimization, specified as a structure. Modifies the effect of the `OptimizeHyperparameters` name-value pair. All fields in the structure are optional.

Field Name	Values	Default
<code>Optimizer</code>	<ul style="list-style-type: none"> • <code>'bayesopt'</code> — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. • <code>'gridsearch'</code> — Use grid search with <code>NumGridDivisions</code> values per dimension. • <code>'randomsearch'</code> — Search at random among <code>MaxObjectiveEvaluations</code> points. 	<code>'bayesopt'</code>

Field Name	Values	Default
	'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the <code>commandsortrows(Mdl.ParameterOptim</code>	
AcquisitionFunc	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>For details, see the <code>bayesopt</code> <code>AcquisitionFunctionName</code> name-value pair, or “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEva	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
NumGridDivision	For 'gridsearch', the number of values in each dimension. Can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. Ignored for categorical variables.	10

Field Name	Values	Default
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , plots the best objective function value against iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is <code>'bayesopt'</code> , then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediate	Logical value indicating whether to save results when <code>Optimizer</code> is <code>'bayesopt'</code> . If <code>true</code> , overwrites a workspace variable named <code>'BayesoptResults'</code> at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesoptVerbose</code> name-value pair.	1
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <p><code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.</p>	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code>	<code>Kfold = 5</code>

Field Name	Values	Default
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example: `struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

Mdl — Trained SVM classification model

`ClassificationSVM` model object | `ClassificationPartitionedModel` cross-validated model object

Trained SVM classification model, returned as a `ClassificationSVM` model object or `ClassificationPartitionedModel` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `Leaveout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedModel` cross-validated classifier. Otherwise, `Mdl` is a `ClassificationSVM` classifier.

To reference properties of `Mdl`, use dot notation. For example, enter `Mdl.Alpha` in the Command Window to display the trained Lagrange multipliers.

Limitations

- `fitcsvm` trains SVM classifiers for one- or two-class learning applications. To train SVM classifiers using data with more than two classes, use `fitcecoc`.
- `fitcsvm` supports low- through moderate-dimensional data sets. For high-dimensional data set, use `fitclinear` instead.

Definitions

Box Constraint

A parameter that controls the maximum penalty imposed on margin-violating observations, and aids in preventing overfitting (regularization).

If you increase the box constraint, then the SVM classifier assigns fewer support vectors. However, increasing the box constraint can lead to longer training times.

Gram Matrix

The Gram matrix of a set of n vectors $\{x_1, \dots, x_n; x_j \in R^p\}$ is an n -by- n matrix with element (j,k) defined as $G(x_j, x_k) = \langle \phi(x_j), \phi(x_k) \rangle$, an inner product of the transformed predictors using the kernel function ϕ .

For nonlinear SVM, the algorithm forms a Gram matrix using the predictor matrix columns. The dual formalization replaces the inner product of the predictors with corresponding elements of the resulting Gram matrix (called the “kernel trick”). Subsequently, nonlinear SVM operates in the transformed predictor space to find a separating hyperplane.

Karush-Kuhn-Tucker Complementarity Conditions

KKT complementarity conditions are optimization constraints required for optimal nonlinear programming solutions.

In SVM, the KKT complementarity conditions are

$$\begin{cases} \alpha_j [y_j f(x_j) - 1 + \xi_j] = 0 \\ \xi_j (C - \alpha_j) = 0 \end{cases}$$

for all $j = 1, \dots, n$, where $f(x_j) = \phi(x_j)' \beta + b$, ϕ is a kernel function (see Gram matrix on page 29-2104), and ξ_j is a slack variable. If the classes are perfectly separable, then $\xi_j = 0$ for all $j = 1, \dots, n$.

One-Class Learning

One-class learning, or unsupervised SVM, aims at separating data from the origin in the high-dimensional, predictor space (not the original predictor space), and is an algorithm used for outlier detection.

The algorithm resembles that of SVM for binary classification on page 29-2105. The objective is to minimize dual expression

$$0.5 \sum_{jk} \alpha_j \alpha_k G(x_j, x_k)$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to

$$\sum \alpha_j = nv$$

and $0 \leq \alpha_j \leq 1$ for all $j = 1, \dots, n$. $G(x_j, x_k)$ is element (j, k) of the Gram matrix on page 29-2104.

A small value of v leads to fewer support vectors, and, therefore, a smooth, crude decision boundary. A large value of v leads to more support vectors, and therefore, a curvy, flexible decision boundary. The optimal value of v should be large enough to capture the data complexity and small enough to avoid overtraining. Also, $0 < v \leq 1$.

For more details, see [5].

Support Vector

Support vectors are observations corresponding to strictly positive estimates of $\alpha_1, \dots, \alpha_n$.

SVM classifiers that yield fewer support vectors for a given training set are more desirable.

Support Vector Machines for Binary Classification

The SVM binary classification algorithm searches for an optimal hyperplane that separates the data into two classes. For separable classes, the optimal hyperplane maximizes a *margin* (space that does not contain any observations) surrounding itself,

which creates boundaries for the positive and negative classes. For inseparable classes, the objective is the same, but the algorithm imposes a penalty on the length of the margin for every observation that is on the wrong side of its class boundary.

The linear SVM score function is

$$f(x) = x'\beta + b,$$

where:

- x is an observation (corresponding to a row of X).
- The vector β contains the coefficients that define an orthogonal vector to the hyperplane (corresponding to **Mdl.Beta**). For separable data, the optimal margin length is $2 / \|\beta\|$.
- b is the bias term (corresponding to **Mdl.Bias**).

The root of $f(x)$ for particular coefficients defines a hyperplane. For a particular hyperplane, $f(z)$ is the distance from point z to the hyperplane.

The algorithm searches for the maximum margin length, while keeping observations in the positive ($y = 1$) and negative ($y = -1$) classes separate. Therefore:

- For separable classes, the objective is to minimize $\|\beta\|$ with respect to the β and b subject to $y_j f(x_j) \geq 1$, for all $j = 1, \dots, n$. This is the *primal* formalization for separable classes.
- For inseparable classes, the algorithm uses slack variables (ξ_j) to penalize the objective function for observations that cross the margin boundary for their class. $\xi_j = 0$ for observations that do not cross the margin boundary for their class, otherwise $\xi_j \geq 0$.

The objective is to minimize $0.5\|\beta\|^2 + C\sum \xi_j$ with respect to the β , b , and ξ_j subject to $y_j f(x_j) \geq 1 - \xi_j$ and $\xi_j \geq 0$ for all $j = 1, \dots, n$, and for a positive scalar box constraint on page 29-2104 C . This is the primal formalization for inseparable classes.

The algorithm uses the Lagrange multipliers method to optimize the objective. This introduces n coefficients $\alpha_1, \dots, \alpha_n$ (corresponding to **Mdl.Alpha**). The dual formalizations for linear SVM are:

- For separable classes, minimize

$$0.5 \sum_{j=1}^n \sum_{k=1}^n \alpha_j \alpha_k y_j y_k x_j' x_k - \sum_{j=1}^n \alpha_j$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to $\sum \alpha_j y_j = 0$, $\alpha_j \geq 0$ for all $j = 1, \dots, n$, and Karush-Kuhn-Tucker (KKT) complementarity conditions on page 29-2104.

- For inseparable classes, the objective is the same as for separable classes, except for the additional condition $0 \leq \alpha_j \leq C$ for all $j = 1, \dots, n$.

The resulting score function is

$$\hat{f}(x) = \sum_{j=1}^n \hat{\alpha}_j y_j x' x_j + \hat{b}.$$

\hat{b} is the estimate of the bias and $\hat{\alpha}_j$ is the j th estimate of the vector $\hat{\alpha}$, $j = 1, \dots, n$.

Written this way, the score function is free of the estimate of β as a result of the primal formalization.

The SVM algorithm classifies a new observation, z using $\text{sign}(\hat{f}(z))$.

In some cases, there is a nonlinear boundary separating the classes. *Nonlinear SVM* works in a transformed predictor space to find an optimal, separating hyperplane.

The dual formalization for nonlinear SVM is

$$0.5 \sum_{j=1}^n \sum_{k=1}^n \alpha_j \alpha_k y_j y_k G(x_j, x_k) - \sum_{j=1}^n \alpha_j$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to $\sum \alpha_j y_j = 0$, $0 \leq \alpha_j \leq C$ for all $j = 1, \dots, n$, and the KKT complementarity conditions. $G(x_k, x_j)$ are elements of the Gram matrix on page 29-2104. The resulting score function is

$$\hat{f}(x) = \sum_{j=1}^n \hat{\alpha}_j y_j G(x, x_j) + \hat{b}.$$

For more details, see Understanding Support Vector Machines on page 18-200, [1], and [3].

Tips

- Unless your data set is large, always try to standardize the predictors (see **Standardize**). Standardization makes predictors insensitive to the scales on which they are measured.
- It is good practice to cross-validate using the **KFold** name-value pair argument. The cross-validation results determine how well the SVM classifier generalizes.
- For one-class learning:
 - The default setting for the name-value pair argument **Alpha** can lead to long training times. To speed up training, set **Alpha** to a vector mostly composed of 0s.
 - Set the name-value pair argument **Nu** to a value closer to 0 to yield fewer support vectors, and, therefore, a smoother, but crude decision boundary.
- Sparsity in support vectors is a desirable property of an SVM classifier. To decrease the number of support vectors, set **BoxConstraint** to a large value. This action increases the training time.
- For optimal training time, set **CacheSize** as high as the memory limit on your computer allows.
- If you expect many fewer support vectors than observations in the training set, then you can significantly speed up convergence by shrinking the active set using the name-value pair argument '**ShrinkagePeriod**'. It is good practice to use '**ShrinkagePeriod**', 1000.
- Duplicate observations that are far from the decision boundary do not affect convergence. However, just a few duplicate observations that occur near the decision boundary can slow down convergence considerably. To speed up convergence, specify '**RemoveDuplicates**', true if:
 - Your data set contains many duplicate observations.
 - You suspect that a few duplicate observations fall near the decision boundary.

However, to maintain the original data set during training, `fitcsvm` must temporarily store separate data sets: the original and one without the duplicate observations. Therefore, if you specify `true` for data sets containing few duplicates, then `fitcsvm` consumes close to double the memory of the original data.

Algorithms

- NaN, <undefined>, and empty character vector (' ') values indicate missing values. `fitcsvm` removes entire rows of data corresponding to a missing response. When computing total weights (see the next bullets), `fitcsvm` ignores any weight corresponding to an observation with at least one missing predictor. This action can lead to unbalanced prior probabilities in balanced-class problems. Consequently, observation box constraints might not equal `BoxConstraint`.
- `fitcsvm` removes observations that have zero weight or prior probability.
- For two-class learning, if you specify the cost matrix `C` (see `Cost`), then the software updates the class prior probabilities p (see `Prior`) to p_c by incorporating the penalties described in `C`.

Specifically, `fitcsvm`:

- 1 Computes $p_c^* = p'C$.
- 2 Normalizes p_c^* so that the updated prior probabilities sum 1:

$$p_c = \frac{1}{\sum_{j=1}^K p_{c,j}^*} p_c^*$$

K is the number of classes.

- 3 Resets the cost matrix to the default:

$$C = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

4 Removes observations from the training data corresponding to classes with zero prior probability.

- For two-class learning, `fitcsvm` normalizes all observation weights (see `Weights`) to sum to 1. Then, renormalizes the normalized weights to sum up to the updated, prior probability of the class to which the observation belongs. That is, the total weight for observation j in class k is

$$w_j^* = \frac{w_j}{\sum_{\forall j \in \text{Class } k} w_j} p_{c,k}.$$

w_j is the normalized weight for observation j ; $p_{c,k}$ is the updated prior probability of class k (see previous bullet).

- For two-class learning, `fitcsvm` assigns a box constraint to each observation in the training data. The formula for the box constraint of observation j is

$$C_j = nC_0w_j^*.$$

n is the training sample size, C_0 is the initial box constraint (see `BoxConstraint`), and w_j^* is the total weight of observation j (see previous bullet).

- If you set `'Standardize', true` and any of `'Cost'`, `'Prior'`, or `'Weights'`, then `fitcsvm` standardizes the predictors using their corresponding weighted means and weighted standard deviations. That is, `fitcsvm` standardizes predictor j (x_j) using

$$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.$$

- $\mu_j^* = \frac{1}{\sum_k w_k^*} \sum_k w_k^* x_{jk}$.
- x_{jk} is observation k (row) of predictor j (column).
- $(\sigma_j^*)^2 = \frac{v_1}{v_1^2 - v_2} \sum_k w_k^* (x_{jk} - \mu_j^*)^2$.

- $$v_1 = \sum_j w_j^*.$$
- $$v_2 = \sum_j (w_j^*)^2.$$
- Let p be the proportion of outliers that you expect in the training data. If you set 'OutlierFraction', p , then:
 - For one-class learning, the software trains the bias term such that $100p\%$ of the observations in the training data have negative scores.
 - The software implements *robust learning* for two-class learning. In other words, the software attempts to remove $100p\%$ of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- If your predictor data contains categorical variables, then the software generally uses full dummy encoding for these variables. The software creates one dummy variable for each level of each categorical variable.
 - The **PredictorNames** property stores one element for each of the original predictor variable names. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then **PredictorNames** is a 1-by-3 cell array of character vectors containing the original names of the predictor variables.
 - The **ExpandedPredictorNames** property stores one element for each of the predictor variables, including the dummy variables. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then **ExpandedPredictorNames** is a 1-by-5 cell array of character vectors containing the names of the predictor variables and the new dummy variables.
 - Similarly, the **Beta** property stores one beta coefficient for each predictor, including the dummy variables.
 - The **SupportVectors** property stores the predictor values for the support vectors, including the dummy variables. For example, assume that there are m support vectors and three predictors, one of which is a categorical variable with three levels. Then **SupportVectors** is an n -by-5 matrix.
 - The **X** property stores the training data as originally input. It does not include the dummy variables. When the input is a table, **X** contains only the columns used as predictors.

- For predictors specified in a table, if any of the variables contain ordered (ordinal) categories, the software uses ordinal encoding for these variables.
 - For a variable having k ordered levels, the software creates $k - 1$ dummy variables. The j th dummy variable is -1 for levels up to j , and +1 for levels $j + 1$ through k .
 - The names of the dummy variables stored in the `ExpandedPredictorNames` property indicate the first level with the value +1. The software stores $k - 1$ additional predictor names for the dummy variables, including the names of levels 2, 3, ..., k .
- All solvers implement $L1$ soft-margin minimization.
- `fitcsvm` and `svmtrain` use, among other algorithms, SMO for optimization. The software implements SMO differently between the two functions, but numerical studies show that there is sensible agreement in the results.
- For one-class learning, the software estimates the Lagrange multipliers, $\alpha_1, \dots, \alpha_n$, such that

$$\sum_{j=1}^n \alpha_j = nv.$$

Introduced in R2014a

fitctree

Fit binary classification decision tree for multiclass classification

Syntax

```
tree = fitctree(Tbl,ResponseVarName)
tree = fitctree(Tbl,formula)
tree = fitctree(Tbl,Y)

tree = fitctree(X,Y)

tree = fitctree( ____,Name,Value)
```

Description

`tree = fitctree(Tbl,ResponseVarName)` returns a fitted binary classification decision tree based on the input variables (also known as predictors, features, or attributes) contained in the table `Tbl` and output (response or labels) contained in `ResponseVarName`. The returned binary tree splits branching nodes based on the values of a column of `Tbl`.

`tree = fitctree(Tbl,formula)` returns a fitted binary classification decision tree based on the input variables contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `tree`.

`tree = fitctree(Tbl,Y)` returns a fitted binary classification decision tree based on the input variables contained in the table `Tbl` and output in vector `Y`.

`tree = fitctree(X,Y)` returns a fitted binary classification decision tree based on the input variables contained in matrix `X` and output `Y`. The returned binary tree splits branching nodes based on the values of a column of `X`.

`tree = fitctree(____,Name,Value)` fits a tree with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the algorithm used to find the best split on a categorical predictor, grow a cross-validated tree, or hold out a fraction of the input data for validation.

Examples

Grow a Classification Tree

Grow a classification tree using the `ionosphere` data set.

```
load ionosphere
tc = fitctree(X,Y)
```

```
tc =
  ClassificationTree
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
      NumObservations: 351
```

Control Tree Depth

You can control the depth of the trees using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters. `fitctree` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.

Load the `ionosphere` data set.

```
load ionosphere
```

The default values of the tree depth controllers for growing classification trees are:

- `n - 1` for `MaxNumSplits`. `n` is the training sample size.
- `1` for `MinLeafSize`.
- `10` for `MinParentSize`.

These default values tend to grow deep trees for large training sample sizes.

Train a classification tree using the default values for tree depth control. Cross validate the model using 10-fold cross validation.

```
rng(1); % For reproducibility
MdlDefault = fitctree(X,Y,'CrossVal','on');
```

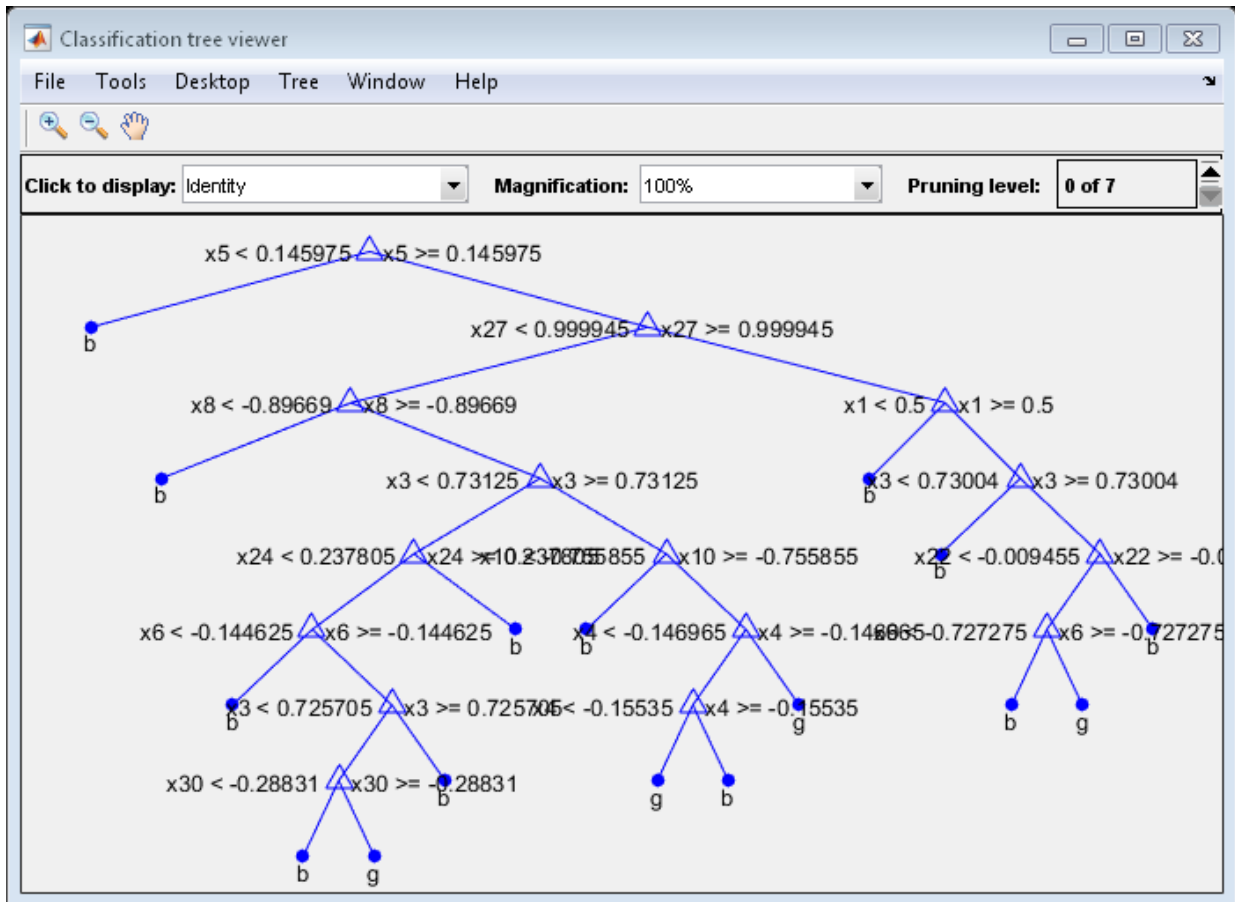

Draw a histogram of the number of imposed splits on the trees. Also, view one of the trees.

```
numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, MdlDefault.Trained);
```

```
figure;
histogram(mdlDefaultNumSplits)
```

```
view(MdlDefault.Trained{1},'Mode','graph')
```

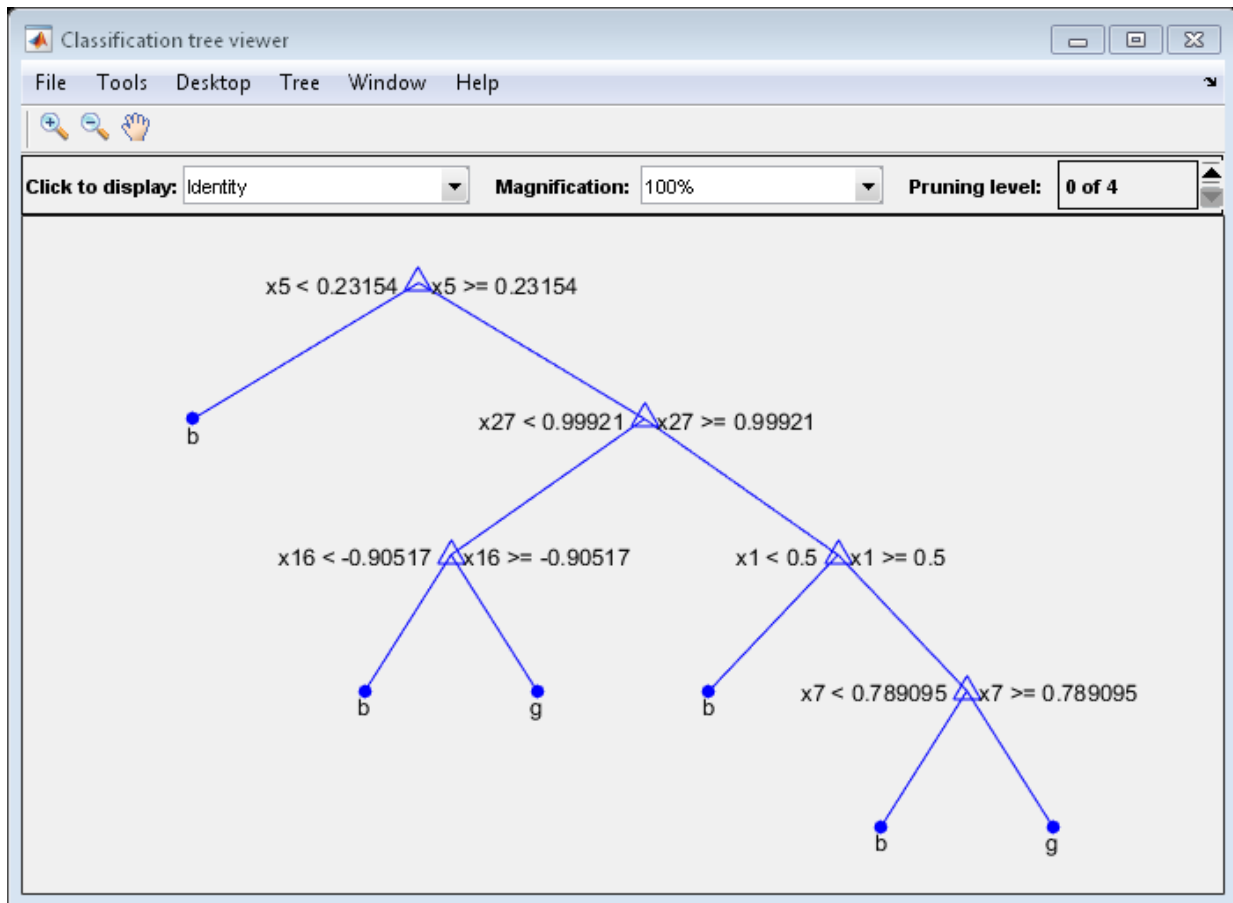

The average number of splits is around 15.

Suppose that you want a classification tree that is not as complex (deep) as the ones trained using the default number of splits. Train another classification tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default classification tree. Cross validate the model using 10-fold cross validation.

```
Mdl7 = fitctree(X,Y,'MaxNumSplits',7,'CrossVal','on');
view(Mdl7.Trained{1},'Mode','graph')
```

Compare the cross validation classification errors of the models.

```
classErrorDefault = kfoldLoss(MdlDefault)
classError7 = kfoldLoss(Mdl7)
```

```
classErrorDefault =
```

```
    0.1140
```

```
classError7 =
```

0.1254

Mdl7 is much less complex and performs only slightly worse than MdlDefault.

Optimize Classification Tree

This example shows how to optimize hyperparameters automatically using `fitctree`. The example uses Fisher's iris data.

Load Fisher's iris data.

```
load fisheriris
```

Optimize the cross-validation loss of the classifier, using the data in `meas` to predict the response in `species`.

```
X = meas;
Y = species;
Mdl = fitctree(X,Y,'OptimizeHyperparameters','auto')
```

```

Unbiased Predictor Importance Estimates

Load the `census1994` data set. Consider a model that predicts a person's salary category given their age, working class, education level, marital status, race, sex, capital gain and loss, and number of working hours per week.

```
load census1994
X = adultdata(:, {'age', 'workClass', 'education_num', 'marital_status', 'race', ...
```

```
'sex', 'capital_gain', 'capital_loss', 'hours_per_week', 'salary'}));
```

Display the number of categories represented in the categorical variables using `summary`.

```
summary(X)
```

Variables:

```
age: 32561×1 double
```

```
Values:
```

Min	17
Median	37
Max	90

```
workClass: 32561×1 categorical
```

```
Values:
```

Federal-gov	960
Local-gov	2093
Never-worked	7
Private	22696
Self-emp-inc	1116
Self-emp-not-inc	2541
State-gov	1298
Without-pay	14
NumMissing	1836

```
education_num: 32561×1 double
```

```
Values:
```

Min	1
Median	10
Max	16

```
marital_status: 32561×1 categorical
```

```
Values:
```

Divorced	4443
Married-AF-spouse	23

Married-civ-spouse	14976
Married-spouse-absent	418
Never-married	10683
Separated	1025
Widowed	993

race: 32561×1 categorical

Values:

Amer-Indian-Eskimo	311
Asian-Pac-Islander	1039
Black	3124
Other	271
White	27816

sex: 32561×1 categorical

Values:

Female	10771
Male	21790

capital_gain: 32561×1 double

Values:

Min	0
Median	0
Max	99999

capital_loss: 32561×1 double

Values:

Min	0
Median	0
Max	4356

hours_per_week: 32561×1 double

Values:

Min	1
-----	---

```

        Median    40
        Max       99

salary: 32561x1 categorical

Values:

    <=50K    24720
    >50K     7841

```

Because there are few categories represented in the categorical variables compared to levels in the continuous variables, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over the categorical variables.

Train a classification tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing observations in the data, specify usage of surrogate splits.

```
Mdl = fitctree(X, 'salary', 'PredictorSelection', 'curvature', ...
    'Surrogate', 'on');
```

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

```
imp = predictorImportance(Mdl);

figure;
bar(imp);
title('Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, `capital_gain` is the most important predictor, followed by `education_num`.

Input Arguments

Tb1 — Sample data

table

Sample data used to train the model, specified as a table. Each row of **Tb1** corresponds to one observation, and each column corresponds to one predictor variable. Optionally, **Tb1** can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element must correspond to one row of the array.

It is good practice to specify the order of the classes using the `ClassNames` name-value pair argument.

Data Types: `char`

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char`

Y — Class labels

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class labels, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. Each row of Y represents the classification of the corresponding row of X.

When fitting the tree, `fitctree` considers NaN, '' (empty character vector), and <undefined> values in Y to be missing values. `fitctree` does not use observations with missing values for Y in the fit.

For numeric Y, consider fitting a regression tree using `fitrtree` instead.

Data Types: `single` | `double` | `char` | `logical` | `cell`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row of X corresponds to one observation, and each column corresponds to one predictor variable.

`fitctree` considers NaN values in X as missing values. `fitctree` does not use observations with all missing values for X in the fit. `fitctree` uses observations with some missing values for X to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Note: You cannot use any cross-validation name-value pair along with `OptimizeHyperparameters`. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair.

Example: 'CrossVal', 'on', 'MinLeafSize', 40 specifies a cross-validated classification tree with a minimum of 40 observations per leaf.

Model Parameters

'AlgorithmForCategorical' — Algorithm for best categorical predictor split

'Exact' | 'PullLeft' | 'PCA' | 'OVAbyClass'

Algorithm to find the best split on a categorical predictor with C categories for data and $K \geq 3$ classes, specified as the comma-separated pair consisting of 'AlgorithmForCategorical' and one of the following values.

Value	Description
'Exact'	Consider all $2^{C-1} - 1$ combinations.
'PullLeft'	Start with all C categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the K classes among the remaining categories. From this sequence, choose the split that has the lowest impurity.
'PCA'	Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all $C - 1$ splits.
'OVAbyClass'	Start with all C categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. From this sequence, choose the split that has the minimum impurity.

`fitctree` automatically selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For $K = 2$ classes, `fitctree` always performs the exact search. To specify a particular algorithm, use the `'AlgorithmForCategorical'` name-value pair argument.

Example: `'AlgorithmForCategorical', 'PCA'`

'CategoricalPredictors' — Categorical predictors list

numeric or logical vector | cell array of character vectors | character matrix | `'all'`

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following:

- A numeric vector with indices from 1 through p , where p is the number of columns of X .
- A logical vector of length p , where a `true` entry means that the corresponding column of X is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length.
- `'all'`, meaning all predictors are categorical.

By default, if the predictor data is in a matrix (X), the software assumes that none of the predictors are categorical. If the predictor data is in a table (`Tbl`), the software assumes that a variable is categorical if it contains, logical values, values of the unordered data type `categorical`, or a cell array of character vectors.

Example: `'CategoricalPredictors', 'all'`

Data Types: `single` | `double` | `char` | `logical` | `cell`

'ClassNames' — Names of classes to use for training

categorical array | cell array of character vectors | character array | logical vector | numeric vector

Names of classes to use for training, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` must be the same data type as Y .

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a', 'b', 'c'}`. To train the model using observations from classes 'a' and 'c' only, specify `'ClassNames', {'a', 'c'}`.

The default is the set of all distinct class names in `Y`.

Example: `'ClassNames', {'b', 'g'}`

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

'Cost' — Cost of misclassification

`square matrix` | `structure`

Cost of misclassification of a point, specified as the comma-separated pair consisting of `'Cost'` and one of the following:

- Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of `Cost`, also specify the `ClassNames` name-value pair argument.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same data type as `Y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if `i~j`, and `Cost(i, j)=0` if `i=j`.

Data Types: `single` | `double` | `struct`

'MaxNumCategories' — Maximum category levels

10 (default) | nonnegative scalar value

Maximum category levels, specified as the comma-separated pair consisting of `'MaxNumCategories'` and a nonnegative scalar value. `fitctree` splits a categorical predictor using the exact search algorithm if the predictor has at most

`MaxNumCategories` levels in the split node. Otherwise, `fitctree` finds the best categorical split using one of the inexact algorithms.

Passing a small value can lead to loss of accuracy and passing a large value can increase computation time and memory overload.

Example: `'MaxNumCategories',8`

'MergeLeaves' — Leaf merge flag

`'on'` (default) | `'off'`

Leaf merge flag, specified as the comma-separated pair consisting of `'MergeLeaves'` and `'on'` or `'off'`.

If `MergeLeaves` is `'on'`, then `fitctree`:

- Merges leaves that originate from the same parent node, and that yields a sum of risk values greater or equal to the risk associated with the parent node
- Estimates the optimal sequence of pruned subtrees, but does not prune the classification tree

Otherwise, `fitctree` does not merge leaves.

Example: `'MergeLeaves','off'`

'MinParentSize' — Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of `'MinParentSize'` and a positive integer value. Each branch node in the tree has at least `MinParentSize` observations. If you supply both `MinParentSize` and `MinLeafSize`, `fitctree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize,2*MinLeafSize)`.

Example: `'MinParentSize',8`

Data Types: `single` | `double`

'PredictorNames' — Predictor variable names

cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `'PredictorNames'` to give the predictor variables in `X` names.
 - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
 - By default, `PredictorNames` is `{x1,x2,...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitctree` uses the predictor variables in `PredictorNames` and the response only in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It good practice to specify the predictors for training using one of `'PredictorNames'` or `formula` only.

Example: `'PredictorNames'`,
`{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: cell

'PredictorSelection' — Algorithm used to select the best split predictor

`'allsplits'` (default) | `'curvature'` | `'interaction-curvature'`

Algorithm used to select the best split predictor at each node, specified as the comma-separated pair consisting of `'PredictorSelection'` and a value in this table.

Value	Description
<code>'allsplits'</code>	Standard CART — Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors [1].
<code>'curvature'</code>	Curvature test — Selects the split predictor that minimizes the p -value of chi-square tests of independence between each predictor and the response [4]. Training speed is similar to standard CART.
<code>'interaction-curvature'</code>	Interaction test — Chooses the split predictor that minimizes the p -value of chi-square tests of independence between each

Value	Description
	predictor and the response, and that minimizes the p -value of a chi-square test of independence between each pair of predictors and response [3]. Training speed can be slower than standard CART.

For 'curvature' and 'interaction-curvature', if all tests yield p -values greater than 0.05, then `fitctree` stops splitting nodes.

Tip:

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [4]. Consider specifying the curvature or interaction test if any of the following are true:
 - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
 - If an analysis of predictor importance is your goal. For more on predictor importance estimation, see `predictorImportance`.
 - Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [3].
 - Prediction speed is unaffected by the value of 'PredictorSelection'.
-

For details on how `fitctree` selects split predictors, see “Node Splitting Rules” on page 29-2149.

Example: 'PredictorSelection', 'curvature'

Data Types: char

'Prior' — Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- A character vector:
 - `'empirical'` determines class probabilities from class frequencies in `Y`. If you pass observation weights, `fitctree` uses the weights to compute the class probabilities.
 - `'uniform'` sets all class probabilities equal.
- A vector (one scalar value for each class). To specify the class order for the corresponding elements of `Prior`, also specify the `ClassNames` name-value pair argument.
- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as `Y`
 - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `weights` and `prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior','uniform'`

'Prune' — Flag to estimate optimal sequence of pruned subtrees

`'on'` (default) | `'off'`

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of `'Prune'` and `'on'` or `'off'`.

If `Prune` is `'on'`, then `fitctree` grows the classification tree without pruning it, but estimates the optimal sequence of pruned subtrees. Otherwise, `fitctree` grows the classification tree without estimating the optimal sequence of pruned subtrees.

To prune a trained `ClassificationTree` model, pass it to `prune`.

Example: `'Prune','off'`

'PruneCriterion' — Pruning criterion

`'error'` (default) | `'impurity'`

Pruning criterion, specified as the comma-separated pair consisting of `'PruneCriterion'` and `'error'` or `'impurity'`.

Example: `'PruneCriterion','impurity'`

'ResponseName' — Response variable name

`'Y'` (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector representing the name of the response variable.

This name-value pair is not valid when using the ResponseVarName or formula input arguments.

Example: 'ResponseName', 'IrisType'

'ScoreTransform' — Score transform function

'none' | character vector | function handle

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a function handle for transforming scores. Your function must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Alternatively, you can specify one of the following character vectors representing a built-in transformation function.

Value	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

Example: 'ScoreTransform', 'logit'

'Surrogate' — Surrogate decision splits flag

'off' (default) | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When set to 'on', `fitctree` finds at most 10 surrogate splits at each branch node.
- When set to 'all', `fitctree` finds all surrogate splits at each branch node. The 'all' setting can use considerable time and memory.
- When set to a positive integer value, `fitctree` finds at most the specified number of surrogate splits at each branch node.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also lets you compute measures of predictive association between predictors. For more details, see “Node Splitting Rules” on page 29-2149.

Example: 'Surrogate', 'on'

Data Types: `single` | `double` | `char`

'Weights' — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The software weights the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector. For example, if weights vector `W` is stored as `Tbl.W`, then specify it as 'W'. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors when training the model.

`fitctree` normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: `single` | `double`

Cross Validation

'CrossVal' — Flag to grow cross-validated decision tree

'off' (default) | 'on'

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of 'CrossVal' and 'on' or 'off'.

If 'on', `fitctree` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. You can only use one of these four arguments at a time when creating a cross-validated tree.

Alternatively, cross validate `tree` later using the `crossval` method.

Example: 'CrossVal', 'on'

'CVPartition' — Partition for cross-validated tree

`cvpartition` object

Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`.

If you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

'Holdout' — Fraction of data for holdout validation

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout', 0.1

Data Types: `single` | `double`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets

- 3** Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',8`

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. Specify `'on'` to use leave-one-out cross-validation.

If you use `'Leaveout'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'KFold'` name-value pair arguments.

Example: `'Leaveout','on'`

Hyperparameters

'MaxNumSplits' — Maximal number of decision splits

`size(X,1) - 1` (default) | positive integer

Maximal number of decision splits (or branch nodes), specified as the comma-separated pair consisting of `'MaxNumSplits'` and a positive integer. `fitctree` splits `MaxNumSplits` or fewer branch nodes. For more details on splitting behavior, see [Algorithms](#) on page 29-2149.

Example: `'MaxNumSplits',5`

Data Types: `single` | `double`

'MinLeafSize' — Minimum number of leaf node observations

`1` (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of `'MinLeafSize'` and a positive integer value. Each leaf has at least `MinLeafSize` observations per tree leaf. If you supply both `MinParentSize` and `MinLeafSize`, `fitctree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize,2*MinLeafSize)`.

Example: `'MinLeafSize',3`

Data Types: `single` | `double`

'NumVariablesToSample' — Number of predictors to select at random for each split
'all' | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NumVariablesToSample'` and a positive integer value. You can also specify `'all'` to use all available predictors.

Example: `'NumVariablesToSample',3`

Data Types: `single` | `double`

'SplitCriterion' — Split criterion
'gdi' (default) | 'twoing' | 'deviance'

Split criterion, specified as the comma-separated pair consisting of `'SplitCriterion'` and `'gdi'` (Gini's diversity index), `'twoing'` for the twoing rule, or `'deviance'` for maximum deviance reduction (also known as cross entropy).

Example: `'SplitCriterion','deviance'`

Hyperparameter Optimization

'OptimizeHyperparameters' — Parameters to optimize
'none' (default) | 'auto' | 'all' | cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'MinLeafSize'}`
- `'all'` — Optimize all eligible parameters.
- Cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitctree` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 29-3219. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note: `OptimizeHyperparameters` values override any values you set using other name-value pairs. For example, setting `OptimizeHyperparameters` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitctree` are:

- `MaxNumSplits` — `fitctree` searches among integers, by default log-scaled in the range `[1,max(2,NumObservations-1)]`.
- `MinLeafSize` — `fitctree` searches among integers, by default log-scaled in the range `[1,max(2,floor(NumObservations/2))]`.
- `SplitCriterion` — For two classes, `fitctree` searches among `'gdi'` and `'deviance'`. For three or more classes, `fitctree` also searches among `'twoing'`.
- `NumVariablesToSample` — `fitctree` does not optimize over this hyperparameter. If you pass `NumVariablesToSample` as a parameter name, `fitctree` simply uses the full number of predictors. However, `fitcensemble` does optimize over this hyperparameter.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitctree',meas,species);
params(1).Range = [1,30];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression, and the misclassification rate for classification. To control the iterative display, set the `HyperparameterOptimizationOptions` name-value pair, `Verbose` field. To control the plots, set the `HyperparameterOptimizationOptions` name-value pair, `ShowPlots` field.

For an example, see “Optimize Classification Tree” on page 29-2119.

Example: `'auto'`

Data Types: `char` | `cell`

'HyperparameterOptimizationOptions' — Options for optimization
structure

Options for optimization, specified as a structure. Modifies the effect of the `OptimizeHyperparameters` name-value pair. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the <code>commandsortrows(Mdl.ParameterOptim</code></p>	'bayesopt'
AcquisitionFunc	<ul style="list-style-type: none"> 'expected-improvement-per-second-plus' 'expected-improvement' 'expected-improvement-plus' 'expected-improvement-per-second' 'lower-confidence-bound' 'probability-of-improvement' <p>For details, see the <code>bayesopt</code> <code>AcquisitionFunctionName</code> name-value pair, or “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEva	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'

Field Name	Values	Default
NumGridDivision	For 'gridsearch', the number of values in each dimension. Can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. Ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If true, plots the best objective function value against iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters.	true
SaveIntermediate	Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.	false
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the bayesoptVerbose name-value pair.	1

Field Name	Values	Default
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code>	<code>Kfold = 5</code>
Holdout	A scalar in the range $(0, 1)$ representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example: `struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

tree — Classification tree

classification tree object

Classification tree, returned as a classification tree object.

Using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method. Instead, use `kfoldpredict` to predict responses for observations not used for training.

Otherwise, `tree` is of class `ClassificationTree`, and you can use the `predict` method to make predictions.

Definitions

Curvature Test

The *curvature test* is a statistical test assessing the null hypothesis that two variables are unassociated.

The curvature test between predictor variable x and y is conducted using this process.

- 1 If x is continuous, then partition it into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.
- 2 For each level in the partitioned predictor $j = 1 \dots J$ and class in the response $k = 1, \dots, K$, compute the weighted proportion of observations in class k

$$\hat{\pi}_{jk} = \sum_{i=1}^n I\{y_i = k\} w_i.$$

w_i is the weight of observation i , $\sum w_i = 1$, I is the indicator function, and n is the sample size. If all observations have the same weight, then $\hat{\pi}_{jk} = \frac{n_{jk}}{n}$, where n_{jk} is the number of observations in level j of the predictor that are in class k .

- 3 Compute the test statistic

$$t = n \sum_{k=1}^K \sum_{j=1}^J \frac{(\hat{\pi}_{jk} - \hat{\pi}_{j+} \hat{\pi}_{+k})^2}{\hat{\pi}_{j+} \hat{\pi}_{+k}}$$

$\hat{\pi}_{j+} = \sum_k \hat{\pi}_{jk}$, that is, the marginal probability of observing the predictor at level

j . $\hat{\pi}_{+k} = \sum_j \hat{\pi}_{jk}$, that is the marginal probability of observing class k . If n is large

enough, then t is distributed as a χ^2 with $(K - 1)(J - 1)$ degrees of freedom.

- 4 If the p -value for the test is less than 0.05, then reject the null hypothesis that there is no association between x and y .

When determining the best split predictor at each node, the standard CART algorithm prefers to select continuous predictors that have many levels. Sometimes, such a selection can be spurious and can also mask more important predictors that have fewer levels, such as categorical predictors.

The curvature test can be applied instead of standard CART to determine the best split predictor at each node. In that case, the best split predictor variable is the one that minimizes the significant p -values (those less than 0.05) of curvature tests between each predictor and the response variable. Such a selection is robust to the number of levels in individual predictors.

Note: If levels of a predictor are pure for a particular class, then `fitctree` merges those levels. Therefore, in step 3 of the algorithm, J can be less than the actual number of levels in the predictor. For example, if x has 4 levels, and all observations in bins 1 and 2 belong to class 1, then those levels are pure for class 1. Consequently, `fitctree` merges the observations in bins 1 and 2, and J reduces to 3.

For more details on how the curvature test applies to growing classification trees, see “Node Splitting Rules” on page 29-2149 and [4].

Impurity and Node Error

`ClassificationTree` splits nodes based on either *impurity* or *node error*.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a *pure* node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance (`'deviance'`) — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- **Twoing rule ('twoing')** — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R) \left(\sum_i |L(i) - R(i)| \right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- **Node error** — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is $1 - p(j)$.

Interaction Test

The *interaction test* is a statistical test that assesses the null hypothesis that there is no interaction between a pair of predictor variables and the response variable.

The interaction test assessing the association between predictor variables x_1 and x_2 with respect to y is conducted using this process.

- 1 If x_1 or x_2 is continuous, then partition that variable into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.
- 2 Create the nominal variable z with $J = J_1 J_2$ levels that assigns an index to observation i according to which levels of x_1 and x_2 it belongs. Remove any levels of z that do not correspond to any observations.

3 Conduct a curvature test between z and y .

When growing decision trees, if there are important interactions between pairs of predictors, but there are also many other less important predictors in the data, then standard CART tends to miss the important interactions. However, conducting curvature and interaction tests for predictor selection instead can improve detection of important interactions, which can yield more accurate decision trees.

For more details on how the interaction test applies to growing decision trees, see “Curvature Test” on page 29-2145, “Node Splitting Rules” on page 29-2149 and [3].

Predictive Measure of Association

The *predictive measure of association* is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_j L_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_j R_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Surrogate Decision Splits

A *surrogate decision split* is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association.

Tip

By default, Prune is 'on'. However, this specification does not prune the classification tree. To prune a trained classification tree, pass the classification tree to prune.

Algorithms

Node Splitting Rules

fitctree uses these processes to determine how to split node t .

- For standard CART (that is, if PredictorSelection is 'allpairs') and for all predictors x_i , $i = 1, \dots, p$:
 - 1 fitctree computes the weighted impurity of node t , i_t . For supported impurity measures, see SplitCriterion.
 - 2 fitctree estimates the probability that an observation is in node t using

$$P(T) = \sum_{j \in T} w_j.$$

w_j is the weight of observation j , and T is the set of all observation indices in node t . If you do not specify Prior or Weights, then $w_j = 1/n$, where n is the sample size.

- 3 **fitctree** sorts x_i in ascending order. Each element of the sorted predictor is a splitting candidate or cut point. **fitctree** stores any indices corresponding to missing values in the set T_U , which is the unsplit set.
- 4 **fitctree** determines the best way to split node t using x_i by maximizing the impurity gain (ΔI) over all splitting candidates. That is, for all splitting candidates in x_i :
 - a **fitctree** splits the observations in node t into left and right child nodes (t_L and t_R , respectively).
 - b **fitctree** computes ΔI . Suppose that for a particular splitting candidate, t_L and t_R contain observation indices in the sets T_L and T_R , respectively.
 - If x_i does not contain any missing values, then the impurity gain for the current splitting candidate is

$$\Delta I = P(T)i_t - P(T_L)i_{t_L} - P(T_R)i_{t_R}.$$

- If x_i contains missing values then, assuming that the observations are missing at random, the impurity gain is

$$\Delta I_U = P(T - T_U)i_t - P(T_L)i_{t_L} - P(T_R)i_{t_R}.$$

$T - T_U$ is the set of all observation indices in node t that are not missing.

- If you use surrogate decision splits, then:
 - i **fitctree** computes the predictive measures of association between the decision split $x_j < u$ and all possible decision splits $x_k < v, j \neq k$.
 - ii **fitctree** sorts the possible alternative decision splits in descending order by their predictive measure of association with the optimal split. The surrogate split is the decision split yielding the largest measure.
 - iii **fitctree** decides the child node assignments for observations with a missing value for x_i using the surrogate split. If the surrogate predictor also contains a missing value, then **fitctree** uses the decision split with the second largest measure, and so on, until there are no other surrogates. It is possible for **fitctree** to split two different observations at node t using two different surrogate splits.

For example, suppose the predictors x_1 and x_2 are the best and second best surrogates, respectively, for the predictor x_i , $i \notin \{1,2\}$, at node t . If observation m of predictor x_i is missing (i.e., x_{mi} is missing), but x_{m1} is not missing, then x_1 is the surrogate predictor for observation x_{mi} . If observations $x_{(m+1),i}$ and $x_{(m+1),1}$ are missing, but $x_{(m+1),2}$ is not missing, then x_2 is the surrogate predictor for observation $m+1$.

- iv `fitctree` uses the appropriate impurity gain formula. That is, if `fitctree` fails to assign all missing observations in node t to children nodes using surrogate splits, then the impurity gain is ΔI_U . Otherwise, `fitctree` uses ΔI for the impurity gain.
- c `fitctree` chooses the candidate that yields the largest impurity gain.

`fitctree` splits the predictor variable at the cut point that maximizes the impurity gain.

- For the curvature test (that is, if `PredictorSelection` is 'curvature'):
 - 1 `fitctree` conducts curvature tests between each predictor and the response for observations in node t .
 - If all p -values are at least 0.05, then `fitctree` does not split node t .
 - If there is a minimal p -value, then `fitctree` chooses the corresponding predictor to split node t .
 - If more than one p -value is zero due to underflow, then `fitctree` applies standard CART to the corresponding predictors to choose the split predictor.
 - 2 If `fitctree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).
- For the interaction test (that is, if `PredictorSelection` is 'interaction-curvature'):
 - 1 For observations in node t , `fitctree` conducts curvature tests between each predictor and the response and interaction tests between each pair of predictors and the response.
 - If all p -values are at least 0.05, then `fitctree` does not split node t .
 - If there is a minimal p -value and it is the result of a curvature test, then `fitctree` chooses the corresponding predictor to split node t .

- If there is a minimal p -value and it is the result of an interaction test, then `fitctree` chooses the split predictor using standard CART on the corresponding pair of predictors.
 - If more than one p -value is zero due to underflow, then `fitctree` applies standard CART to the corresponding predictors to choose the split predictor.
- 2 If `fitctree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

Tree Depth Control

- If `MergeLeaves` is 'on' and `PruneCriterion` is 'error' (which are the default values for these name-value pair arguments), then the software applies pruning only to the leaves and by using classification error. This specification amounts to merging leaves that share the most popular class per leaf.
- To accommodate `MaxNumSplits`, `fitctree` splits all nodes in the current *layer*, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds `MaxNumSplits`, `fitctree` follows this procedure:
 - 1 Determine how many branch nodes in the current layer must be unsplit so that there are at most `MaxNumSplits` branch nodes.
 - 2 Sort the branch nodes by their impurity gains.
 - 3 Unsplit the number of least successful branches.
 - 4 Return the decision tree grown so far.

This procedure produces maximally balanced trees.

- The software splits branch nodes layer by layer until at least one of these events occurs:
 - There are `MaxNumSplits` branch nodes.
 - A proposed split causes the number of observations in at least one branch node to be fewer than `MinParentSize`.
 - A proposed split causes the number of observations in at least one leaf node to be fewer than `MinLeafSize`.
 - The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see `PruneCriterion`), does not improve for all proposed splits in a layer). A

special case is when all nodes are pure (i.e., all observations in the node have the same class).

- For values 'curvature' or 'interaction-curvature' of PredictorSelection, all tests yield p -values greater than 0.05.

MaxNumSplits and MinLeafSize do not affect splitting at their default values. Therefore, if you set 'MaxNumSplits', splitting might stop due to the value of MinParentSize, before MaxNumSplits splits occur.

Parallelization

For dual-core systems and above, fitctree parallelizes training decision trees using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

```

Description

`mdl = fitglm(tbl)` returns a generalized linear model fit to variables in the table or dataset array `tbl`. By default, `fitglm` takes the last variable as the response variable.

`mdl = fitglm(X,y)` returns a generalized linear model of the responses `y`, fit to the data matrix `X`.

`mdl = fitglm(____,modelspec)` returns a generalized linear model of the type you specify in `modelspec`.

`mdl = fitglm(____,Name,Value)` returns a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables are categorical, the distribution of the response variable, and the link function to use.

Examples

Fit a Logistic Regression Model

Make a logistic binomial model of the probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the `hospital` dataset array.

```
load hospital
dsa = hospital;
```

Specify the model using a formula that allows up to two-way interactions between the variables age, weight, and sex. Smoker is the response variable.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Fit a logistic binomial model.

```
mdl = fitglm(dsa,modelspec,'Distribution','binomial')
```

```
mdl =
```

Generalized linear regression model:

```
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
Distribution = Binomial
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

100 observations, 93 error degrees of freedom

Dispersion: 1

Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

All of the p-values (under pValue) are large. This means none of the coefficients are significant. The large *P*-value for the test of the model, 0.535, indicates that this model might not differ statistically from a constant model.

GLM for Poisson Response

Create sample data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
```

```
X = randn(100,7);
mu = exp(X(:,[1 3 6])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = fitglm(X,y,'linear','Distribution','poisson')
```

```
mdl =
```

Generalized linear regression model:

```
log(y) ~ 1 + x1 + x2 + x3 + x4 + x5 + x6 + x7
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	0.88723	0.070969	12.502	7.3149e-36
x1	0.44413	0.052337	8.4858	2.1416e-17
x2	0.0083388	0.056527	0.14752	0.88272
x3	0.21518	0.063416	3.3932	0.00069087
x4	-0.058386	0.065503	-0.89135	0.37274
x5	-0.060824	0.073441	-0.8282	0.40756
x6	0.34267	0.056778	6.0352	1.5878e-09
x7	0.04316	0.06146	0.70225	0.48252

100 observations, 92 error degrees of freedom

Dispersion: 1

Chi^2-statistic vs. constant model: 119, p-value = 1.55e-22

The p-values of 2.14e-17, 0.00069, and 1.58e-09 indicate that the coefficients of the variables x1, x3, and |x6| are statistically significant.

- “Generalized Linear Model Workflow” on page 12-40

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-58).

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

modelspec — Model specification

character vector specifying the model | t -by- $(p+1)$ terms matrix | character vector of the form 'Y ~ terms'

Model specification, which is the starting model for `stepwiseglm`, specified as one of the following:

- Character vector specifying the type of model.

Character Vector	Model Type
'constant'	Model contains only a constant (intercept) term.

Character Vector	Model Type
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- t -by- $(p+1)$ matrix, namely “Terms Matrix” on page 29-2164, specifying terms to include in model, where t is the number of terms and p is the number of predictor variables, and plus one is for the response variable.
- Character vector representing a “Formula” on page 29-2167 in the form `'Y ~ terms'`, where the `terms` are in “Wilkinson Notation” on page 29-2168.

Example: `'quadratic'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Distribution', 'normal', 'link', 'probit', 'Exclude', [23,59]` specifies that the distribution of the response is normal, and instructs `fitglm` to use the probit link function and exclude the 23rd and 59th observations from the fit.

'BinomialSize' — Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter n for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double`

'CategoricalVars' — Categorical variables

cell array of character vectors | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of character vectors of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

'DispersionFlag' — Indicator to compute dispersion parameter

false for `'binomial'` and `'poisson'` distributions (default) | true

Indicator to compute dispersion parameter for `'binomial'` and `'poisson'` distributions, specified as the comma-separated pair consisting of `'DispersionFlag'` and one of the following.

<code>true</code>	Estimate a dispersion parameter when computing standard errors
<code>false</code>	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

Example: `'DispersionFlag', true`

'Distribution' — Distribution of the response variable

`'normal'` (default) | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of the response variable, specified as the comma-separated pair consisting of `'Distribution'` and one of the following.

<code>'normal'</code>	Normal distribution
<code>'binomial'</code>	Binomial distribution
<code>'poisson'</code>	Poisson distribution
<code>'gamma'</code>	Gamma distribution
<code>'inverse gaussian'</code>	Inverse Gaussian distribution

Example: `'Distribution', 'gamma'`

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude', [2,3]`

Example: `'Exclude', logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

'Intercept' — Indicator for constant term

`true` (default) | `false`

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either `true` to include or `false` to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector, not a formula or matrix.

Example: 'Intercept',false

'Link' — Link function

The canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
'comprologlog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: <ul style="list-style-type: none"> • <code>S.Link</code> — The link function • <code>S.Inverse</code> — The inverse link function • <code>S.Derivative</code> — The derivative of the link function 	$f(\mu) = \mathbf{S}.\text{Link}(\mu)$ $\mu = \mathbf{S}.\text{Inverse}(Xb)$	

The link function defines the relationship $f(\mu) = X^*b$ between the mean response μ and the linear combination of predictors X^*b .

For more information on the canonical link functions, see [Definitions](#).

Example: 'Link', 'probit'

'Offset' — Offset variable

[] (default) | vector | character vector

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

`fitglm` and `stepwiseglm` use `Offset` as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is $\mu \sim \text{Offset} + (\text{terms involving real predictors})$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: single | double | char

'PredictorVars' — Predictor variables

cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The character vectors should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars', [2,3]

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `cell`

'ResponseVar' — Response variable

last column in `tbl` (default) | character vector containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char`

'VarNames' — Names of variables in fit

`{'x1','x2',...,'xn','y'}` (default) | cell array of character vectors

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of character vectors including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `cell`

'Weights' — Observation weights

`ones(n,1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: `single` | `double`

Output Arguments

`mdl` — Generalized linear model

`GeneralizedLinearModel` object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a `GeneralizedLinearModel` object.

For properties and methods of the generalized linear model object, `mdl`, see the `GeneralizedLinearModel` class page.

Definitions

Terms Matrix

A terms matrix is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and plus one is for the response variable.

The value of $T(i, j)$ is the exponent of variable j in term i . Suppose there are three predictor variables A , B , and C :

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
dsa = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
```

```
hospital.Smoker, 'VarNames', {'Sex', 'BloodPressure', 'Age', 'Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0     0     0     0
1     0     0     0
0     0     1     0
0     0     0     1
```

Redefine the dataset array.

```
dsa = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker, 'VarNames', {'BloodPressure', 'Sex', 'Age', 'Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0     0     0     0
0     1     0     0
0     0     1     0
0     0     0     1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes

the main effect and two-way interaction terms for the variables, **Acceleration** and **Weight**, and a second-order term for the variable, **Weight**.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```

0     0     0
1     0     0
0     1     0
1     1     0
0     2     0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

```
Linear regression model:
```

```
y ~ 1 + x1*x2 + x2^2
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

```
Number of observations: 94, Error degrees of freedom: 89
```

```
Root Mean Squared Error: 4.1
```

```
R-squared: 0.751, Adjusted R-Squared 0.739
```

```
F-statistic vs. constant model: 67, p-value = 4.99e-26
```

Only the intercept and **x2** term, which correspond to the **Weight** variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = stepwiselm(X,MPG,[0 0 0], 'upper', T)
```

```
1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28
```

```
mdl =
```

```
Linear regression model:
```

```
y ~ 1 + x2
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

```
Number of observations: 94, Error degrees of freedom: 92
```

```
Root Mean Squared Error: 4.13
```

```
R-squared: 0.738, Adjusted R-Squared 0.735
```

```
F-statistic vs. constant model: 259, p-value = 1.64e-28
```

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

Formula

A formula for model specification is a character vector of the form ' $Y \sim terms$ '

where

- Y is the response name.
- $terms$ contains
 - Variable names
 - + means include the next variable
 - - means do not include the next variable
 - : defines an interaction, a product of terms
 - * defines an interaction **and all lower-order terms**
 - ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower order terms as well
 - () groups terms

Note: Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a B^2 term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because B^2 includes a B term.

' $Y \sim A + B + C + A:B$ ' includes an $A*B$ term.

' $Y \sim A*B + C$ ' is the same as the previous example because $A*B = A + B + A:B$.

' $Y \sim A*B*C - A:B:C$ ' has all interactions among A , B , and C , except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of A with each of the other variables.

Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
- For methods such as `plotResiduals` or `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

Alternative Functionality

Use `stepwiseglm` to select a model specification automatically. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Tall Arrays

This function supports tall arrays for out-of-memory data with some limitations.

- If any input argument to `fitglm` is a tall array, then all of the other inputs must be tall arrays as well. This includes nonempty variables supplied with the `'Weights'`, `'Exclude'`, `'Offset'`, and `'BinomialSize'` name-value pairs.
- The default number of iterations is 5. You can change the number of iterations using the `'Options'` name-value pair to pass in an options structure. Create an options structure using `statset` to specify a different value for `MaxIter`.
- For tall data, `fitglm` returns a `CompactGeneralizedLinearModel` object that contains most of the same properties as a `GeneralizedLinearModel` object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these `GeneralizedLinearModel` properties:
 - `Diagnostics`
 - `Fitted`
 - `Offset`
 - `ObservationInfo`
 - `ObservationNames`
 - `Residuals`
 - `Steps`
 - `Variables`

You can compute the residuals directly from the compact object returned by `GLM = fitglm(X,Y)` using

```
RES = Y - predict(GLM,X);
```

```
S = sqrt(GLM.SSE/GLM.DFE);  
histogram(RES,linspace(-3*S,3*S,51))
```

For more information, see “Tall Arrays” (MATLAB).

fitglme

Fit generalized linear mixed-effects model

Syntax

```
glme = fitglme(tbl,formula)
glme = fitglme(tbl,formula,Name,Value)
```

Description

`glme = fitglme(tbl,formula)` returns a generalized linear mixed-effects model, `glme`. The model is specified by `formula` and fitted to the predictor variables in the table or dataset array, `tbl`.

`glme = fitglme(tbl,formula,Name,Value)` returns a generalized linear mixed-effects model using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the distribution of the response, the link function, or the covariance pattern of the random-effects terms.

Examples

Fit a Generalized Linear Mixed-Effects Model

Load the sample data.

```
data = fullfile(matlabroot,'examples','stats','mfr.mat');
load(data)
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time_dev** and **temp_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time_dev**, **temp_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}).$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- **defects_{ij}** is the number of defects observed in the batch produced by factory *i* during batch *j*.
- **μ_{ij}** is the mean number of defects corresponding to factory *i* (where $i = 1, 2, \dots, 20$) during batch *j* (where $j = 1, 2, \dots, 5$).
- **newprocess_{ij}**, **time_dev_{ij}**, and **temp_dev_{ij}** are the measurements for each variable that correspond to factory *i* during batch *j*. For example, **newprocess_{ij}** indicates whether the batch produced by factory *i* during batch *j* used the new process.

- `supplier_Cij` and `supplier_Bij` are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory *i* during batch *j*.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory *i* that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
  'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', ...
  'DummyVarCoding', 'effects');
```

Display the model.

```
disp(glme)
```

Generalized linear mixed-effects model fit by ML

Model information:

Number of observations	100
Fixed effects coefficients	6
Random effects coefficients	20
Covariance parameters	1
Distribution	Poisson
Link	Log
FitMethod	Laplace

Formula:

```
defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1 | factory)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
416.35	434.58	-201.17	402.35

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	1.4689	0.15988	9.1875	94	9.8194e-15
'newprocess'	-0.36766	0.17755	-2.0708	94	0.041122
'time_dev'	-0.094521	0.82849	-0.11409	94	0.90941
'temp_dev'	-0.28317	0.9617	-0.29444	94	0.76907
'supplier_C'	-0.071868	0.078024	-0.9211	94	0.35936
'supplier_B'	0.071072	0.07739	0.91836	94	0.36078

Lower	Upper
1.1515	1.7864
-0.72019	-0.015134
-1.7395	1.5505
-2.1926	1.6263
-0.22679	0.083051
-0.082588	0.22473

Random effects covariance parameters:

Group: factory (20 Levels)

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	0.31381

Group: Error

Name	Estimate
'sqrt(Dispersion)'	1

The **Model information** table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a **Poisson** distribution, the link function is **Log**, and the fit method is **Laplace**.

Formula indicates the model specification using Wilkinson's notation.

The **Model fit statistics** table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (**AIC**), Bayesian information criterion (**BIC**) values, log likelihood (**LogLikelihood**), and deviance (**Deviance**) values.

The **Fixed effects coefficients** table indicates that **fitglm** returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (**Name**) contains the name of each fixed-effects coefficient, column 2 (**Estimate**) contains its estimated value, and column 3 (**SE**) contains the standard error of the coefficient. Column 4 (**tStat**) contains the *t*-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (**DF**) and column 6 (**pValue**) contain the degrees of freedom and *P*-value that correspond to the *t*-statistic, respectively. The last two columns (**Lower** and **Upper**) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

Random effects covariance parameters displays a table for each grouping variable (here, only **factory**), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, **std** indicates that **fitglm** returns the standard deviation of the random effect associated with the **factory** predictor, which has

an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by `fitglme` does not provide confidence intervals for the random-effects parameters. To compute and display these values, use `covarianceParameters`.

- “Fit a Generalized Linear Mixed-Effects Model” on page 12-77

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-58). You must specify the model for the variables using `formula`.

Data Types: `single` | `double` | `char` | `cell`

formula — Formula for model specification

character vector of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a character vector of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. The character vector is case sensitive. For a full description, see “Formula” on page 29-2189.

Example: `'y ~ treatment + (1|block)'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

`'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding','`

specifies the response variable distribution as Poisson, the link function as log, the fit method as Laplace, and dummy variable coding where the coefficients sum to 0.

'BinomialSize' — Number of trials for binomial distribution

1 (default) | scalar value | vector | variable name

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value, a vector of the same length as the response, or the name of a variable in the input table. If you specify the name of a variable, then the variable must be of the same length as the response. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

Data Types: `single` | `double`

'CheckHessian' — Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of `'CheckHessian'` and either `false` or `true`. Default is `false`.

Specify `'CheckHessian'` as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

If you specify `'FitMethod'` as `'MPL'` or `'REML'`, then the covariance of the fixed effects and the covariance parameters is based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Example: `'CheckHessian', true`

'CovarianceMethod' — Method to compute covariance of estimated parameters

'conditional' (default) | 'JointHessian'

Method to compute covariance of estimated parameters, specified as the comma-separated pair consisting of `'CovarianceMethod'` and either `'conditional'` or `'JointHessian'`. If you specify `'conditional'`, then `fitglm` computes a fast approximation to the covariance of fixed effects given the estimated covariance parameters. It does not compute the covariance of covariance parameters. If you specify `'JointHessian'`, then `fitglm` computes the joint covariance of fixed effects and covariance parameters via the observed information matrix using the Laplacian loglikelihood.

If you specify 'FitMethod' as 'MPL' or 'REML', then the covariance of the fixed effects and the covariance parameters is based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Example: 'CovarianceMethod', 'JointHessian'

'CovariancePattern' — Pattern of covariance matrix

'FullCholesky' | 'Isotropic' | 'Full' | 'Diagonal' | 'CompSymm' | square symmetric logical matrix | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and 'FullCholesky', 'Isotropic', 'Full', 'Diagonal', 'CompSymm', a square symmetric logical matrix, or a cell array containing character vectors or logical matrices.

If there are R random-effects terms, then the value of 'CovariancePattern' must be a cell array of length R , where each element r of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

Value	Description
'FullCholesky'	Full covariance matrix using the Cholesky parameterization. <code>fitglme</code> estimates all elements of the covariance matrix.
'Isotropic'	Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like $\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$

Value	Description
	where σ^2_1 is the common variance of the random-effects terms.
'Full'	Full covariance matrix, using the log-Cholesky parameterization. <code>fitlme</code> estimates all elements of the covariance matrix.
'Diagonal'	<p>Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.</p> $\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$
'CompSymm'	<p>Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like</p> $\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$ <p>where σ^2_{b1} is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .</p>

Value	Description
PAT	Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if $PAT(a, b) = \text{false}$, then the (a, b) element of the corresponding covariance matrix is constrained to be 0.

For scalar random-effects terms, the default is 'Isotropic'. Otherwise, the default is 'FullCholesky'.

Example: 'CovariancePattern', 'Diagonal'

Example: 'CovariancePattern', {'Full', 'Diagonal'}

'DispersionFlag' — Indicator to compute dispersion parameter

false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

Value	Description
true	Estimate a dispersion parameter when computing standard errors
false	Use the theoretical value of 1.0 when computing standard errors

'DispersionFlag' only applies if 'FitMethod' is 'MPL' or 'REML'.

The fitting function always estimates the dispersion for other distributions.

Example: 'DispersionFlag', true

'Distribution' — Distribution of the response variable

'Normal' (default) | 'Binomial' | 'Poisson' | 'Gamma' | 'InverseGaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

Value	Description
'Normal'	Normal distribution

Value	Description
'Binomial'	Binomial distribution
'Poisson'	Poisson distribution
'Gamma'	Gamma distribution
'InverseGaussian'	Inverse Gaussian distribution

Example: 'Distribution', 'Binomial'

'DummyVarCoding' — Coding to use for dummy variables

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

Value	Description
'reference'	Default. Coefficient for first category set to 0.
'effects'	Coefficients sum to 0.
'full'	One dummy variable for each category.

Example: 'DummyVarCoding', 'effects'

'EBMethod' — Method used to approximate empirical Bayes estimates of random effects

'Auto' (default) | 'LineSearchNewton' | 'TrustRegion2D' | 'fsolve'

Method used to approximate empirical Bayes estimates of random effects, specified as the comma-separated pair consisting of 'EBMethod' and one of the following.

- 'Auto'
- 'LineSearchNewton'
- 'TrustRegion2D'
- 'fsolve'

'Auto' is similar to 'LineSearchNewton' but uses a different convergence criterion and does not display iterative progress. 'Auto' and 'LineSearchNewton' may fail for non-canonical link functions. For non-canonical link functions, 'TrustRegion2D' or 'fsolve' are recommended. You must have Optimization Toolbox to use 'fsolve'.

Example: 'EBMethod', 'LineSearchNewton'

'EBOptions' — Options for empirical Bayes optimization
structure

Options for empirical Bayes optimization, specified as the comma-separated pair consisting of 'EBOptions' and a structure containing the following.

Value	Description
'TolFun'	Relative tolerance on the gradient norm. Default is 1e-6.
'TolX'	Absolute tolerance on the step size. Default is 1e-8.
'MaxIter'	Maximum number of iterations. Default is 100.
'Display'	'off', 'iter', or 'final'. Default is 'off'.

If `EBMethod` is 'Auto' and `FitMethod` is 'Laplace', `TolFun` is the relative tolerance on the linear predictor of the model, and the `'Display'` option does not apply.

If `EBMethod` is 'fsolve', then `'EBOptions'` must be specified as an object created by `optimoptions('fsolve')`.

Data Types: struct

'Exclude' — Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the generalized linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude', [13,67]`

Data Types: single | double | logical

'FitMethod' — Method for estimating model parameters

'MPL' (default) | 'REML' | 'Laplace' | 'ApproximateLaplace'

Method for estimating model parameters, specified as the comma-separated pair consisting of 'FitMethod' and one of the following.

- 'MPL' — Maximum pseudo likelihood
- 'REML' — Restricted maximum pseudo likelihood
- 'Laplace' — Maximum likelihood using Laplace approximation
- 'ApproximateLaplace' — Maximum likelihood using approximate Laplace approximation with fixed effects profiled out

Example: 'FitMethod', 'REML'

'InitPLIterations' — Initial number of pseudo likelihood iterations

10 (default) | integer value in the range [1,∞)

Initial number of pseudo likelihood iterations used to initialize parameters for ApproximateLaplace and Laplace fit methods, specified as the comma-separated pair consisting of 'InitPLIterations' and an integer value greater than or equal to 1.

Data Types: single | double

'Link' — Link function

'identity' | 'log' | 'logit' | 'probit' | 'comploglog' | 'reciprocal' | scalar value | structure

Link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Value	Description
'identity'	$g(\mu) = \mu$ This is the default for the normal distribution.
'log'	$g(\mu) = \log(\mu)$ This is the default for the Poisson distribution.
'logit'	$g(\mu) = \log(\mu / (1 - \mu))$ This is the default for the binomial distribution.

Value	Description
'loglog'	$g(\mu) = \log(-\log(\mu))$
'probit'	$g(\mu) = \text{norminv}(\mu)$
'comploglog'	$g(\mu) = \log(-\log(1-\mu))$
'reciprocal'	$g(\mu) = \mu.^{-1}$
Scalar value P	$g(\mu) = \mu.^P$
Structure S	<p>A structure containing four fields whose values are function handles with the following names:</p> <ul style="list-style-type: none"> • <code>S.Link</code> — Link function • <code>S.Derivative</code> — Derivative • <code>S.SecondDerivative</code> — Second derivative • <code>S.Inverse</code> — Inverse of link <p>Specification of <code>S.SecondDerivative</code> can be omitted if <code>FitMethod</code> is <code>MPL</code> or <code>REMP</code>, or if <code>S</code> is the canonical link for the specified distribution.</p>

The default link function used by `fitglm` is the canonical link that depends on the distribution of the response.

Response Distribution	Canonical Link Function
'Normal'	'identity'
'Binomial'	'logit'
'Poisson'	'log'
'Gamma'	-1
'InverseGaussian'	-2

Example: 'Link', 'log'

Data Types: single | double | struct

'MuStart' — Starting value for conditional mean

scalar value

Starting value for conditional mean, specified as the comma-separated pair consisting of 'MuStart' and a scalar value. Valid values are as follows.

Response Distribution	Valid Values
'Normal'	(-Inf, Inf)
'Binomial'	(0, 1)
'Poisson'	(0, Inf)
'Gamma'	(0, Inf)
'InverseGaussian'	(0, Inf)

Data Types: single | double

'Offset' — Offsetzeros(*n*, 1) (default) | *n*-by-1 vector of scalar values

Offset, specified as the comma-separated pair consisting of 'Offset' and an *n*-by-1 vector of scalar values, where *n* is the length of the response vector. You can also specify the variable name of an *n*-by-1 vector of scalar values. 'Offset' is used as an additional predictor that has a coefficient value fixed at 1.0.

Data Types: single | double

'Optimizer' — Optimization algorithm

'quasnewton' (default) | 'fminsearch' | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

Value	Description
'quasnewton'	Uses a trust region based quasi-Newton optimizer. You can change the options of the algorithm using <code>statset('fitglm')</code> . If you do not specify the options, then <code>fitglm</code> uses the default options of <code>statset('fitglm')</code> .

Value	Description
'fminsearch'	Uses a derivative-free Nelder-Mead method. You can change the options of the algorithm using <code>optimset('fminsearch')</code> . If you do not specify the options, then <code>fitglm</code> uses the default options of <code>optimset('fminsearch')</code> .
'fminunc'	Uses a line search-based quasi-Newton method. You must have Optimization Toolbox to specify this option. You can change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you do not specify the options, then <code>fitglm</code> uses the default options of <code>optimoptions('fminunc')</code> with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminsearch'

'OptimizerOptions' — Options for optimization algorithm

structure returned by `statset` | structure returned by `optimset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('fitglm')`, a structure created by `optimset('fminsearch')`, or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminsearch', then use `optimset('fminsearch')` to change the options of the algorithm. If 'Optimizer' is 'fminsearch' and you do not supply 'OptimizerOptions', then the defaults used in `fitglm` are the default options created by `optimset('fminsearch')`.
- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the defaults used in `fitglm` are the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.

- If 'Optimizer' is 'quasnewton', then use `statset('fitglm')` to change the optimization parameters. If 'Optimizer' is 'quasnewton' and you do not change the optimization parameters using `statset`, then `fitglm` uses the default options created by `statset('fitglm')`.

The 'quasnewton' optimizer uses the following fields in the structure created by `statset('fitglm')`.

'ToIFun' — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

'ToIX' — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

'MaxIter' — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

'Display' — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

'PLIterations' — Maximum number of pseudo likelihood iterations

100 (default) | positive integer value

Maximum number of pseudo likelihood (PL) iterations, specified as the comma-separated pair consisting of 'PLIterations' and a positive integer value. PL is used for fitting the model if 'FitMethod' is 'MPL' or 'REML'. For other 'FitMethod' values, PL iterations are used to initialize parameters for subsequent optimization.

Example: 'PLIterations',200

Data Types: single | double

'PLTolerance' — Relative tolerance factor for pseudo likelihood iterations

1e-08 (default) | positive scalar value

Relative tolerance factor for pseudo likelihood iterations, specified as the comma-separated pair consisting of `'PLTolerance'` and a positive scalar value.

Example: `'PLTolerance', 1e-06`

Data Types: `single` | `double`

'StartMethod' — Method to start iterative optimization

`'default'` (default) | `'random'`

Method to start iterative optimization, specified as the comma-separated pair consisting of `'StartMethod'` and either of the following.

Value	Description
<code>'default'</code>	An internally defined default value
<code>'random'</code>	A random initial value

Example: `'StartMethod', 'random'`

'UseSequentialFitting' — Initial fitting type

`false` (default) | `true`

, specified as the comma-separated pair consisting of `'UseSequentialFitting'` and either `false` or `true`. If `'UseSequentialFitting'` is `false`, all maximum likelihood methods are initialized using one or more pseudo likelihood iterations. If `'UseSequentialFitting'` is `true`, the initial values from pseudo likelihood iterations are refined using `'ApproximateLaplace'` for `'Laplace'` fitting.

Example: `'UseSequentialFitting', true`

'Verbose' — Indicator to display optimization process on screen

0 (default) | 1 | 2

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of `'Verbose'` and 0, 1, or 2. If `'Verbose'` is specified as 1 or 2, then `fitglm` displays the progress of the iterative model-fitting process. Specifying `'Verbose'` as 2 displays iterative optimization information from the individual pseudo likelihood iterations. Specifying `'Verbose'` as 1 omits this display.

The setting for `'Verbose'` overrides the field `'Display'` in `'OptimizerOptions'`.

Example: 'Verbose', true

'Weights' — Observation weights

vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n -by-1 vector of nonnegative scalar values, where n is the number of observations. If the response distribution is binomial or Poisson, then 'Weights' must be a vector of positive integers.

Data Types: single | double

Output Arguments

glm — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Definitions

Formula

In general, a formula for model specification is a character vector of the form 'y ~ terms'. For the generalized linear mixed-effects models, this formula is in the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)', where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, y
- Predictor variables, X_j , which can be continuous or grouping variables
- Grouping variables, g_1, g_2, \dots, g_R ,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, or cell arrays of character vectors.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix X , `random1` is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1 , and similarly `randomR` is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R . You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$)
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for generalized linear mixed-effects model specification.

Examples:

Formula	Description
<code>'y ~ X1 + X2'</code>	Fixed effects for the intercept, $X1$ and $X2$. This is equivalent to <code>'y ~ 1 + X1 + X2'</code> .
<code>'y ~ -1 + X1 + X2'</code>	No intercept and fixed effects for $X1$ and $X2$. The implicit intercept term is suppressed by including <code>-1</code> .

Formula	Description
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

Introduced in R2014b

fitgmdist

Fit Gaussian mixture distribution to data

Syntax

```
GMMModel = fitgmdist(X,k)  
GMMModel = fitgmdist(X,k,Name,Value)
```

Description

`GMMModel = fitgmdist(X,k)` returns a Gaussian mixture distribution model (`GMMModel`) with `k` components fitted to data (`X`).

`GMMModel = fitgmdist(X,k,Name,Value)` returns a Gaussian mixture distribution model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify a regularization value or the covariance type.

Examples

Cluster Data Using a Gaussian Mixture Model

Generate data from a mixture of two bivariate Gaussian distributions.

```
mu1 = [1 2];  
Sigma1 = [2 0; 0 0.5];  
mu2 = [-3 -5];  
Sigma2 = [1 0; 0 1];  
rng(1); % For reproducibility  
X = [mvnrnd(mu1,Sigma1,1000);mvnrnd(mu2,Sigma2,1000)];
```

Fit a Gaussian mixture model. Specify that there are two components.

```
GMMModel = fitgmdist(X,2);
```

Plot the data over the fitted Gaussian mixture model contours.

```
figure  
y = [zeros(1000,1);ones(1000,1)];
```

```

h = gscatter(X(:,1),X(:,2),y);
hold on
ezcontour(@(x1,x2)pdf(GMMModel,[x1 x2]),get(gca,{'XLim','YLim'}))
title('\bf Scatter Plot and Fitted Gaussian Mixture Contours')
legend(h,'Model 0','Model1')
hold off

```

Regularize Gaussian Mixture Model Estimation

Generate data from a mixture of two bivariate Gaussian distributions. Create a third predictor that is the sum of the first and second predictors.

```

mu1 = [1 2];
Sigma1 = [1 0; 0 1];
mu2 = [3 4];

```

```
Sigma2 = [0.5 0; 0 0.5];
rng(3); % For reproducibility
X1 = [mvnrnd(mu1,Sigma1,100);mvnrnd(mu2,Sigma2,100)];
X = [X1,X1(:,1)+X1(:,2)];
```

The columns of X are linearly dependent. This can cause ill-conditioned covariance estimates.

Fit a Gaussian mixture model to the data. You can use `try / catch` statements to help manage error messages.

```
rng(1); % Reset seed for common start values
try
    GMMModel = fitgmdist(X,2)
catch exception
    disp('There was an error fitting the Gaussian mixture model')
    error = exception.message
end
```

```
There was an error fitting the Gaussian mixture model
```

```
error =
```

```
    'Ill-conditioned covariance created at iteration 2.'
```

The covariance estimates are ill-conditioned. Consequently, optimization stops and an error appears.

Fit a Gaussian mixture model again, but use regularization.

```
rng(3); % Reset seed for common start values
GMMModel = fitgmdist(X,2,'RegularizationValue',0.1)
```

```
GMMModel =
```

```
Gaussian mixture distribution with 2 components in 3 dimensions
```

```
Component 1:
```

```
Mixing proportion: 0.536725
```

```
Mean:      2.8831      3.9506      6.8338
```

```
Component 2:
```

```
Mixing proportion: 0.463275
```

```
Mean:      0.8813      1.9758      2.8571
```

In this case, the algorithm converges to a solution due to regularization.

Select the Number of Gaussian Mixture Model Components Using PCA

Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example shows how to explore the data, and try to get an initial guess at the number of components using principal component analysis.

Load Fisher's iris data set.

```
load fisheriris
classes = unique(species)
```

```
classes =  
  
3×1 cell array  
  
    'setosa'  
    'versicolor'  
    'virginica'
```

The data set contains three classes of iris species. The analysis proceeds as if this is unknown.

Use principal component analysis to reduce the dimension of the data to two dimensions for visualization.

```
[~,score] = pca(meas,'NumComponents',2);
```

Fit three Gaussian mixture models to the data by specifying 1, 2, and 3 components. Increase the number of optimization iterations to 1000. Use dot notation to store the final parameter estimates. By default, the software fits full and different covariances for each component.

```
GMMModels = cell(3,1); % Preallocation  
options = statset('MaxIter',1000);  
rng(1); % For reproducibility  
  
for j = 1:3  
    GMMModels{j} = fitgmdist(score,j,'Options',options);
```

```
fprintf('\n GM Mean for %i Component(s)\n',j)
Mu = GMModels{j}.mu
end
```

```
GM Mean for 1 Component(s)
```

```
Mu =
```

```
1.0e-14 *
-0.2743 -0.0870
```

```
GM Mean for 2 Component(s)
```

```
Mu =
```

```
1.3212 -0.0954
-2.6424 0.1909
```

```
GM Mean for 3 Component(s)
```

```
Mu =
```

```
0.4856 -0.1287
1.4484 -0.0904
-2.6424 0.1909
```

`GMModels` is a cell array containing three, fitted `gmdistribution` models. The means in the three component models are different, suggesting that the model distinguishes among the three iris species.

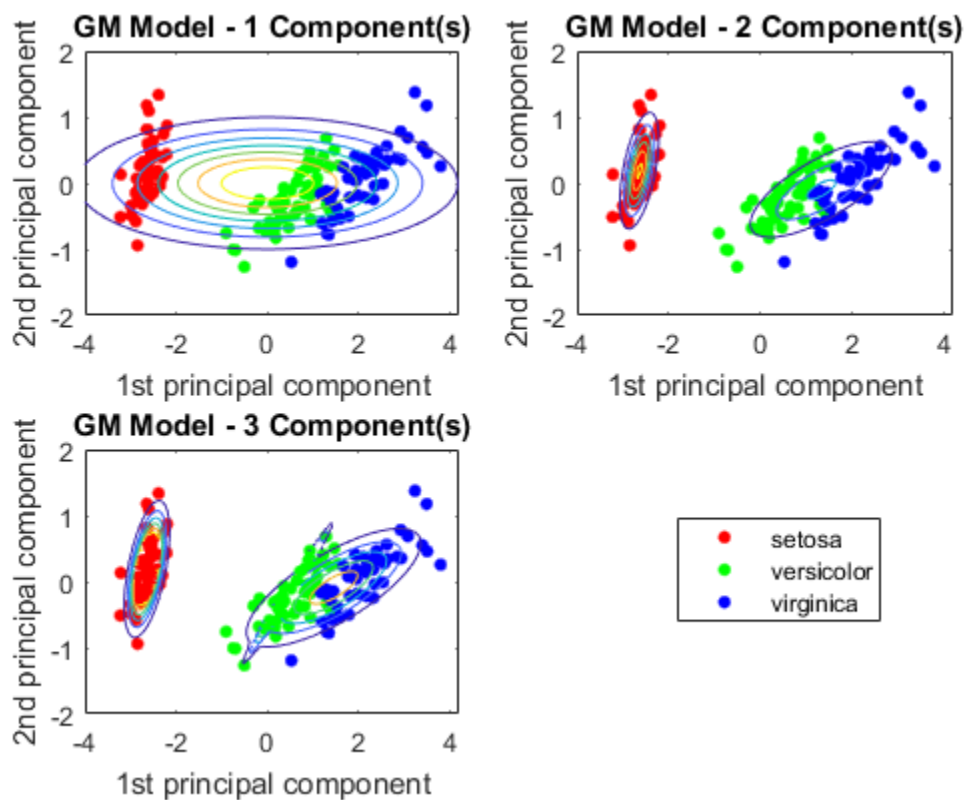

Plot the scores over the fitted Gaussian mixture model contours. Since the data set includes labels, use `gscatter` to distinguish between the true number of components.

```
figure
for j = 1:3
    subplot(2,2,j)
    h1 = gscatter(score(:,1),score(:,2),species);
    h = gca;
    hold on
    ezcontour(@(x1,x2)pdf(GMModels{j},[x1 x2]),...
```

```

    [h.XLim h.YLim],100)
    title(sprintf('GM Model - %i Component(s)',j));
    xlabel('1st principal component');
    ylabel('2nd principal component');
    if(j ~= 3)
        legend off;
    end
    hold off
end
g = legend(h1);
g.Position = [0.7 0.25 0.1 0.1];

```

The three-component Gaussian mixture model, in conjunction with PCA, looks like it distinguishes between the three iris species.

There are other options you can use to help select the appropriate number of components for a Gaussian mixture model. For example,

- Compare multiple models with varying numbers of components using information criteria, e.g., AIC or BIC.
- Estimate the number of clusters using `evalclusters`, which supports, the Calinski-Harabasz criterion and the gap statistic, or other criteria.

Determine the Best Gaussian Mixture Fit Using AIC

Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example uses the AIC fit statistic to help you choose the best fitting Gaussian mixture model over varying numbers of components.

Generate data from a mixture of two bivariate Gaussian distributions.

```
mu1 = [1 1];
Sigma1 = [0.5 0; 0 0.5];
mu2 = [2 4];
Sigma2 = [0.2 0; 0 0.2];
rng(1);
X = [mvnrnd(mu1,Sigma1,1000);mvnrnd(mu2,Sigma2,1000)];

plot(X(:,1),X(:,2),'ko')
title('Scatter Plot')
xlim([min(X(:)) max(X(:))]) % Make axes have the same scale
ylim([min(X(:)) max(X(:))])
```

Supposing that you do not know the underlying parameter values, the scatter plots suggests:

- There are two components.
- The variances between the clusters are different.
- The variance within the clusters is the same.
- There is no covariance within the clusters.

Fit a two-component Gaussian mixture model. Based on the scatter plot inspection, specify that the covariance matrices are diagonal. Print the final iteration and loglikelihood statistic to the Command Window by passing a `statset` structure as the value of the `Options` name-value pair argument.

```
options = statset('Display','final');
GMMModel = fitgmdist(X,2,'CovarianceType','diagonal','Options',options);
```

```
11 iterations, log-likelihood = -4787.38
```

GMMModel is a fitted gmdistribution model.

Examine the AIC over varying numbers of components.

```
AIC = zeros(1,4);
GMMModels = cell(1,4);
options = statset('MaxIter',500);
for k = 1:4
    GMMModels{k} = fitgmdist(X,k,'Options',options,'CovarianceType','diagonal');
    AIC(k) = GMMModels{k}.AIC;
end
```

```
[minAIC,numComponents] = min(AIC);
numComponents
```

```
BestModel = GMMModels{numComponents}
```

```
numComponents =
```

```
2
```

```
BestModel =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
```

```
Component 1:
```

```
Mixing proportion: 0.501719
```

```
Mean:    1.9824    4.0013
```

```
Component 2:
```

```
Mixing proportion: 0.498281
```

```
Mean:    0.9880    1.0511
```

The smallest AIC occurs when the software fits the two-component Gaussian mixture model.

Set Initial Values When Fitting Gaussian Mixture Models

Gaussian mixture model parameter estimates might vary with different initial values. This example shows how to control initial values when you fit Gaussian mixture models using `fitgmdist`.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

```
load fisheriris
X = meas(:,3:4);
```

Fit a Gaussian mixture model to the data using default initial values. There are three iris species, so specify $k = 3$ components.

```
rng(10); % For reproducibility
GMMModel1 = fitgmdist(X,3);
```

By default, the software:

- 1 Implements the “k-means++ Algorithm for Initialization” to choose $k = 3$ initial cluster centers.
- 2 Sets the initial covariance matrices as diagonal, where element (j, j) is the variance of $X(:, j)$.
- 3 Treats the initial mixing proportions as uniform.

Fit a Gaussian mixture model by connecting each observation to its label.

```
y = ones(size(X,1),1);
y(strcmp(species,'setosa')) = 2;
y(strcmp(species,'virginica')) = 3;

GMMModel2 = fitgmdist(X,3,'Start',y);
```

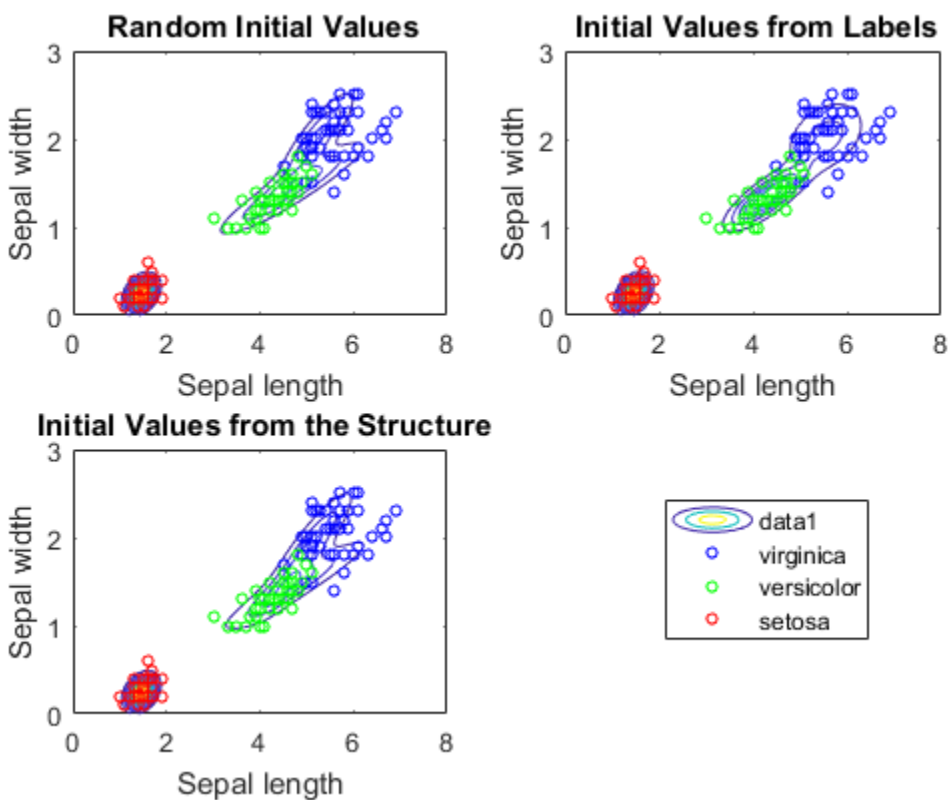

Fit a Gaussian mixture model by explicitly specifying the initial means, covariance matrices, and mixing proportions.

```
Mu = [1 1; 2 2; 3 3];
Sigma(:,:,1) = [1 1; 1 2];
Sigma(:,:,2) = 2*[1 1; 1 2];
Sigma(:,:,3) = 3*[1 1; 1 2];
PComponents = [1/2,1/4,1/4];
S = struct('mu',Mu,'Sigma',Sigma,'ComponentProportion',PComponents);
```

```
GMMModel3 = fitgmdist(X,3,'Start',S);
```

Use `gscatter` to plot a scatter diagram that distinguishes between the iris species. For each model, plot the fitted Gaussian mixture model contours.

```
figure
subplot(2,2,1)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
haxis = gca;
xlim = haxis.XLim;
ylim = haxis.YLim;
d = (max([xlim ylim])-min([xlim ylim]))/1000;
[X1Grid,X2Grid] = meshgrid(xlim(1):d:xlim(2),ylim(1):d:ylim(2));
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMMModel1,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Random Initial Values}');
xlabel('Sepal length');
ylabel('Sepal width');
legend off;
hold off
subplot(2,2,2)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMMModel2,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Initial Values from Labels}');
xlabel('Sepal length');
ylabel('Sepal width');
legend off;
hold off
subplot(2,2,3)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMMModel3,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Initial Values from the Structure}');
xlabel('Sepal length');
ylabel('Sepal width');
legend('Location',[0.7,0.25,0.1,0.1]);
hold off
```

According to the counters, GMMModel2 seems to suggest a slight trimodality, while the others suggest bimodal distributions.

Display the estimated component means.

```
table(GMMModel1.mu, GMMModel2.mu, GMMModel3.mu, 'VariableNames', ...
      {'Model1', 'Model2', 'Model3'})
```

ans =

3×3 table

Model1

Model2

Model3

5.2115	2.0119	4.2857	1.3339	1.4604	0.2429
1.461	0.24423	1.462	0.246	4.7509	1.4629
4.6829	1.4429	5.5507	2.0316	5.0158	1.8592

`GMMode12` seems to distinguish between the iris species the best.

- “Clustering Using Gaussian Mixture Models” on page 16-28

Input Arguments

X — Data

numeric matrix

Data to which the Gaussian mixture model is fit, specified as a numeric matrix.

The rows of `X` correspond to observations, and columns correspond to variables.

`NaN`s indicate missing values. The software removes rows of `X` containing at least one `NaN` before fitting, which decreases the effective sample size.

Data Types: `double`

k — Number of components

positive integer

Number of components to use when fitting Gaussian mixture model, specified as a positive integer. For example, if you specify `k = 3`, then the software fits a Gaussian mixture model with three distinct means, covariances matrices, and component proportions to the data (`X`).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'RegularizationValue',0.1,'CovarianceType','diagonal'` specifies a regularization parameter value of 0.1 and to fit diagonal covariance matrices.

'CovarianceType' — Type of covariance matrix`'full' (default) | 'diagonal'`

Type of covariance matrix to fit to the data, specified as the comma-separated pair consisting of `'CovarianceType'` and either `'diagonal'` or `'full'`.

If you set `'diagonal'`, then the software fits diagonal covariance matrices. In this case, the software estimates $k \cdot d$ covariance parameters, where d is the number of columns in X (i.e., $d = \text{size}(X,2)$).

Otherwise, the software fits full covariance matrices. In this case, the software estimates $k \cdot d \cdot (d+1) / 2$ covariance parameters.

Example: `'CovarianceType', 'diagonal'`

Data Types: char

'Options' — Iterative EM algorithm optimization options`statset options structure`

Iterative EM algorithm optimization options, specified as the comma-separated pair consisting of `'Options'` and a `statset options structure`.

This table describes the available name-value pair arguments.

Name	Value
<code>'Display'</code>	<p><code>'final'</code>: Display the final output.</p> <p><code>'iter'</code>: Display iterative output to the Command Window for some functions; otherwise display the final output.</p> <p><code>'off'</code>: Do not display optimization information.</p>
<code>'MaxIter'</code>	Positive integer indicating the maximum number of iterations allowed. The default is 100
<code>'TolFun'</code>	Positive scalar indicating the termination tolerance for the loglikelihood function value. The default is $1e-6$.

Example:

```
'Options',statset('Display','final','MaxIter',1500,'TolFun',1e-5)
```

'ProbabilityTolerance' — Tolerance for posterior probabilities

1e-8 (default) | nonnegative scalar value in range [0,1e-6]

Tolerance for posterior probabilities, specified as the comma-separated pair consisting of `ProbabilityTolerance` and a nonnegative scalar value in the range [0,1e-6].

In each iteration, after the estimation of posterior probabilities, `fitgmdist` sets any posterior probability that is not larger than the tolerance value to zero. Using a nonzero tolerance might speed up `fitgmdist`.

Example: `'ProbabilityTolerance',0.0000025`

'RegularizationValue' — Regularization parameter value

0 (default) | nonnegative scalar

Regularization parameter value, specified as the comma-separated pair consisting of `'RegularizationValue'` and a nonnegative scalar.

Set `RegularizationValue` to a small positive scalar to ensure that the estimated covariance matrices are positive definite.

Example: `'RegularizationValue',0.01`

Data Types: `double`

'Replicates' — Number of times to repeat EM algorithm

1 (default) | positive integer

Number of times to repeat the EM algorithm using a new set of initial values, specified as the comma-separated pair consisting of `'Replicates'` and a positive integer.

If `Replicates` is greater than 1, then:

- The name-value pair argument `Start` must be `plus` (the default) or `randSample`.
- `GMMModel` is the fit with the largest loglikelihood.

Example: `'Replicates',10`

Data Types: `double`

'SharedCovariance' — Flag indicating whether all covariance matrices are identical

logical false (default) | logical true

Flag indicating whether all covariance matrices are identical (i.e., fit a pooled estimate), specified as the comma-separated pair consisting of 'SharedCovariance' and either logical value false or true.

If SharedCovariance is true, then all k covariance matrices are equal, and the number of covariance parameters is scaled down by a factor of k .

'Start' — Initial value setting method

'plus' (default) | 'randSample' | vector of integers | structure array

Initial value setting method, specified as the comma-separated pair consisting of 'Start' and 'randSample', 'plus', a vector of integers, or a structure array.

The value of Start determines the initial values required by the optimization routine for each Gaussian component parameter — mean, covariance, and mixing proportion. This table summarizes the available options.

Value	Description
'randSample'	The software selects k observations from X at random as initial component means. The mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of $X(:, j)$.
'plus'	The software selects k observations from X using the kmeans++ algorithm. The initial mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of $X(:, j)$.
Vector of integers	A vector of length n (the number of observations) containing an initial guess of the component index for each point. That is, each element is an integer from 1 to k , which corresponds to a component. The software collects all observations corresponding to the same component, computes means, covariances, and mixing proportions for each, and sets the initial values to these statistics.
Structure array	Suppose that there are d variables (i.e., $d = \text{size}(X, 2)$). The structure array, e.g., S , must have three fields: <ul style="list-style-type: none"> $S.mu$: A k-by-d matrix specifying the initial mean of each component

Value	Description
	<ul style="list-style-type: none"> • S.Sigma: A numeric array specifying the covariance matrix of each component. Sigma is one of the following: <ul style="list-style-type: none"> • A d-by-d-by-k array. <code>Sigma(:, :, j)</code> is the initial covariance matrix of component j. • A 1-by-d-by-k array. <code>diag(Sigma(:, :, j))</code> is the initial covariance matrix of component j. • A d-by-d matrix. Sigma is the initial covariance matrix for all components. • A 1-by-d vector. <code>diag(Sigma)</code> is the initial covariance matrix for all components. • S.ComponentProportion: A 1-by-k vector of scalars specifying the initial mixing proportions of each component. The default is uniform.

Example: `'Start', ones(n,1)`

Data Types: `char | double | struct`

Output Arguments

GMMModel — Fitted Gaussian mixture model

`gmdistribution` model

Fitted Gaussian mixture model, returned as a `gmdistribution` model.

Access properties of `GMMModel` using dot notation. For example, display the AIC by entering `GMMModel.AIC`.

Tips

`gmdistribution` might:

- Converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

The following issues might result in an ill-conditioned covariance matrix:

- The number of dimensions of your data is relatively high and there are not enough observations.
- Some of the predictors (variables) of your data are highly correlated.
- Some or all the features are discrete.
- You tried to fit the data to too many components.

In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:

- Preprocess your data to remove correlated features.
 - Set `'SharedCovariance'` to `true` to use an equal covariance matrix for every component.
 - Set `'CovarianceType'` to `'diagonal'`.
 - Use `'RegularizationValue'` to add a very small positive number to the diagonal of every covariance matrix.
 - Try another set of initial values.
- Pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Try another set of initial values to avoid this issue without altering your data or model.

Algorithms

Gaussian Mixture Model Likelihood Optimization

The software optimizes the Gaussian mixture model likelihood using the iterative Expectation-Maximization (EM) algorithm.

k-means++ Algorithm for Initialization

The *k*-means++ algorithm uses an heuristic to find centroid seeds for *k*-means clustering. `fitgmdist` can apply the same principle to initialize the EM algorithm by using the *k*-means++ algorithm to select the initial parameter values for a fitted Gaussian mixture model.

The *k*-means++ algorithm assumes the number of clusters is *k* and chooses the initial parameter values as follows.

- 1 Select the component mixture probability to be the uniform probability $p_i = \frac{1}{k}$, where $i = 1, \dots, k$.
- 2 Select the covariance matrices to be diagonal and identical, where $\sigma_i = \text{diag}(a_1, a_2, \dots, a_k)$ and $a_j = \text{var}(X_j)$.
- 3 Select the first initial component center μ_1 uniformly from all data points in X .
- 4 To choose center j :
 - a Compute the Mahalanobis distances from each observation to each centroid, and assign each observation to its closest centroid.
 - b For $m = 1, \dots, n$ and $p = 1, \dots, j - 1$, select centroid j at random from X with probability

$$\frac{d^2(x_m, \mu_p)}{\sum_{h; x_h \in M_p} d^2(x_h, \mu_p)}$$

where $d(x_m, \mu_p)$ is the distance between observation m and μ_p , and M_p is the set of all observations closest to centroid μ_p and x_m belongs to M_p .

That is, select each subsequent center with a probability proportional to the distance from itself to the closest center that you already chose.

- 5 Repeat step 4 until k centroids are chosen.

“Gaussian Mixture Models” on page 5-151

Introduced in R2014a

fitlm

Create linear regression model

`fitlm` creates a `LinearModel` object. Once you create the object, you can see it in the workspace. You can see all the properties the object contains by clicking on it. You can create plots and do further diagnostic analysis by using methods such as `plot`, `plotResiduals`, and `plotDiagnostics`. For a full list of methods for `LinearModel`, see `methods`.

Syntax

```
mdl = fitlm(tbl)
mdl = fitlm(tbl,modelspec)

mdl = fitlm(X,y)
mdl = fitlm(X,y,modelspec)

mdl = fitlm( ____,Name,Value)
```

Description

`mdl = fitlm(tbl)` returns a linear model fit to variables in the table or dataset array `tbl`. By default, `fitlm` takes the last variable as the response variable.

`mdl = fitlm(tbl,modelspec)` returns a linear model of the type you specify in `modelspec` fit to variables in the table or dataset array `tbl`.

`mdl = fitlm(X,y)` returns a linear model of the responses `y`, fit to the data matrix `X`.

`mdl = fitlm(X,y,modelspec)` returns a linear model of the type you specify in `modelspec` for the responses `y`, fit to the data matrix `X`.

`mdl = fitlm(____,Name,Value)` returns a linear model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables are categorical, perform robust regression, or use observation weights.

Examples

Fit Linear Regression Using Data in Table

Load the sample data.

```
load carsmall
```

Store the variables in a table.

```
tbl = table(Weight,Acceleration,MPG,'VariableNames',{ 'Weight', 'Acceleration', 'MPG' });
```

Display the first five rows of the table.

```
tbl(1:5,:)
```

```
ans =
```

```
5×3 table
```

Weight	Acceleration	MPG
3504	12	18
3693	11.5	15
3436	11	18
3433	12	16
3449	10.5	17

Fit a linear regression model for miles per gallon (MPG).

```
lm = fitlm(tbl,'MPG-Weight+Acceleration')
```

```
lm =
```

Linear regression model:

```
MPG ~ 1 + Weight + Acceleration
```

Estimated Coefficients:

Estimate	SE	tStat	pValue
----------	----	-------	--------

(Intercept)	45.155	3.4659	13.028	1.6266e-22
Weight	-0.0082475	0.00059836	-13.783	5.3165e-24
Acceleration	0.19694	0.14743	1.3359	0.18493

```
Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 4.12
R-squared: 0.743, Adjusted R-Squared 0.738
F-statistic vs. constant model: 132, p-value = 1.38e-27
```

This syntax uses Wilkinson notation to specify the `modelspec`.

The model `'MPG-Weight+Acceleration'` in this example is equivalent to fitting the model using `'linear'` as `modelspec`. For example,

```
lm2 = fitlm(tbl, 'linear');
```

When you use a character vector as `modelspec` and do not specify the response variable, `fitlm` by default accepts the last variable in `tbl` as the response variable and the other variables as the predictor variables. If there are any categorical variables and you use `'linear'` as the `modelspec`, then you must explicitly specify those variables as categorical variables using the `CategoricalVars` name-value pair argument.

Fit Linear Regression Using Specified Model Formula

Fit a linear regression model using a model formula specified by Wilkinson notation.

Load the sample data.

```
load carsmall
```

Store the variables in a table.

```
tbl = table(Weight, Acceleration, Model_Year, MPG, 'VariableNames', {'Weight', 'Acceleration
```

Fit a linear regression model for miles per gallon (MPG) with weight and acceleration as the predictor variables.

```
lm = fitlm(tbl, 'MPG-Weight+Acceleration')
```

```
lm =
```

```
Linear regression model:
MPG ~ 1 + Weight + Acceleration
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	45.155	3.4659	13.028	1.6266e-22
Weight	-0.0082475	0.00059836	-13.783	5.3165e-24
Acceleration	0.19694	0.14743	1.3359	0.18493

Number of observations: 94, Error degrees of freedom: 91

Root Mean Squared Error: 4.12

R-squared: 0.743, Adjusted R-Squared 0.738

F-statistic vs. constant model: 132, p-value = 1.38e-27

The **P**-value of 0.18493 indicates that **Acceleration** does not have a significant impact on **MPG**.

Remove **Acceleration** from the model, and try improving the model by adding the predictor variable **Model_Year**. First define **Model_Year** as a nominal variable.

```
tbl.Model_Year = categorical(tbl.Model_Year);
lm = fitlm(tbl, 'MPG-Weight+Model_Year')
```

lm =

Linear regression model:

MPG ~ 1 + Weight + Model_Year

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	40.11	1.5418	26.016	1.2024e-43
Weight	-0.0066475	0.00042802	-15.531	3.3639e-27
Model_Year_76	1.9291	0.74761	2.5804	0.011488
Model_Year_82	7.9093	0.84975	9.3078	7.8681e-15

Number of observations: 94, Error degrees of freedom: 90

Root Mean Squared Error: 2.92

R-squared: 0.873, Adjusted R-Squared 0.868

F-statistic vs. constant model: 206, p-value = 3.83e-40

Specifying `modelspec` using Wilkinson notation enables you to update the model without having to change the design matrix. `fitlm` uses only the variables that are specified in the formula. It also creates the necessary two dummy indicator variables for the categorical variable `Model_Year`.

Linear Regression with Categorical Predictor

Fit a model of a table that contains a categorical predictor.

Load the `carsmall` data.

```
load carsmall
```

Construct a table containing continuous predictor variable `Weight`, nominal predictor variable `Year`, and response variable `MPG`.

```
tbl = table(MPG,Weight);  
tbl.Year = nominal(Model_Year);
```

Create a fitted model of `MPG` as a function of `Year`, `Weight`, and `Weight^2`. (You don't have to include `Weight` explicitly in your formula because it is a lower-order term of `Weight^2`) and is included automatically.

```
mdl = fitlm(tbl,'MPG ~ Year + Weight^2')
```

```
mdl =
```

Linear regression model:

```
MPG ~ 1 + Weight + Year + Weight^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.78

R-squared: 0.885, Adjusted R-Squared 0.88
 F-Statistic vs. constant model: 172, p-value = 5.52e-41

`fitlm` creates two dummy (indicator) variables for the nominal variate, `Year`. The dummy variable `Year_76` takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year. The corresponding model is

$$\hat{MPG} = 54.206 - 0.0164(\textit{Weight}) + 2.0887(\textit{Year_76}) + 8.1864(\textit{Year_82}) + 1.557e - 06(\textit{Weight}^2)$$

Specify Response and Predictor Variables for Linear Model

Fit a linear regression model to sample data. Specify the response and predictor variables, and include only pairwise interaction terms in the model.

Load sample data.

```
load hospital
```

Fit a linear model with interaction terms to the data. Specify `weight` as the response variable, and `sex`, `age`, and `smoking status` as the predictor variables. Also, specify that `sex` and `smoking status` are categorical variables.

```
mdl = fitlm(hospital, 'interactions', 'ResponseVar', 'Weight', ...
            'PredictorVars', {'Sex', 'Age', 'Smoker'}, ...
            'CategoricalVar', {'Sex', 'Smoker'})
```

```
mdl =
```

Linear regression model:

```
Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	118.7	7.0718	16.785	6.821e-30
Sex_Male	68.336	9.7153	7.0339	3.3386e-10
Age	0.31068	0.18531	1.6765	0.096991
Smoker_1	3.0425	10.446	0.29127	0.77149
Sex_Male:Age	-0.49094	0.24764	-1.9825	0.050377
Sex_Male:Smoker_1	0.9509	3.8031	0.25003	0.80312

```
Age:Smoker_1      -0.07288    0.26275    -0.27737    0.78211
```

```
Number of observations: 100, Error degrees of freedom: 93
Root Mean Squared Error: 8.75
R-squared: 0.898, Adjusted R-Squared 0.892
F-statistic vs. constant model: 137, p-value = 6.91e-44
```

The weight of the patients do not seem to differ significantly according to age, or the status of smoking, or interaction of these factors with patient sex at the 5% significance level.

Fit a Robust Linear Regression Model

Fit a linear regression model using a robust fitting method.

Load the sample data.

```
load hald
```

The `hald` data measures the effect of cement composition on its hardening heat. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The array `heat` contains the heat of hardening after 180 days for each cement sample.

Fit a robust linear model to the data.

```
mdl = fitlm(ingredients,heat,'linear','RobustOpts','on')
```

```
mdl =
```

```
Linear regression model (robust fit):
y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979, Adjusted R-Squared 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07

- “Examine Quality and Adjust the Fitted Model” on page 11-20

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-58). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: single | double | logical

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double`

modelspec — Model specification

'linear' (default) | character vector naming the model | t -by- $(p + 1)$ terms matrix | character vector of the form 'Y ~ terms'

Model specification, specified as one of the following.

- A character vector naming the model.

Character Vector	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- t -by- $(p + 1)$ matrix, namely terms matrix, specifying terms to include in the model, where t is the number of terms and p is the number of predictor variables, and plus 1 is for the response variable.
- A character vector representing a formula in the form

`'Y ~ terms'`,
 where the `terms` are in Wilkinson Notation.

Example: `'quadratic'`

Example: `'y ~ X1 + X2^2 + X1:X2'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Intercept', false, 'PredictorVars', [1,3], 'ResponseVar', 5, 'RobustOpts', 'logistic'` specifies a robust regression model with no constant term, where the algorithm uses the logistic weighting function with the default tuning constant, first and third variables are the predictor variables, and fifth variable is the response variable.

'CategoricalVars' — Categorical variables

cell array of character vectors | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of character vectors of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars', [2,3]`

Example: `'CategoricalVars', logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of **'Exclude'** and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

```
Example: 'Exclude', [2,3]
```

```
Example: 'Exclude', logical([0 1 1 0 0 0])
```

Data Types: single | double | logical

'Intercept' — Indicator for constant term

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of **'Intercept'** and either **true** to include or **false** to remove the constant term from the model.

Use **'Intercept'** only when specifying the model using a character vector, not a formula or matrix.

```
Example: 'Intercept', false
```

'PredictorVars' — Predictor variables

cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of **'PredictorVars'** and either a cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The character vectors should be among the names in `tbl`, or the names you specify using the **'VarNames'** name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

```
Example: 'PredictorVars', [2,3]
```

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `cell`

'ResponseVar' — Response variable

last column in `tbl` (default) | character vector containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char`

'RobustOpts' — Indicator of robust fitting type

'off' (default) | 'on' | character vector | structure with character vector or function handle

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of `'RobustOpts'` and one of the following.

- `'off'` — No robust fitting. `fitlm` uses ordinary least squares.
- `'on'` — Robust fitting. When you use robust fitting, `'bisquare'` weight function is the default.
- Character vector — Name of the robust fitting weight function from the following table. `fitlm` uses the corresponding default tuning constant in the table.
- Structure with the character vector `RobustWgtFun` containing the name of the robust fitting weight function from the following table and optional scalar `Tune` fields — `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. You can choose the name of the robust fitting weight function from this table. If you do not supply a `Tune` field, the fitting function uses the corresponding default tuning constant.

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339
'bisquare' (default)	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(-(r.^2))$	2.985

The value r in the weight functions is

$$r = \text{resid} / (\text{tune} * s * \sqrt{1-h}),$$

where `resid` is the vector of residuals from the previous iteration, `h` is the vector of leverage values from a least-squares fit, and `s` is an estimate of the standard deviation of the error term given by

$$s = \text{MAD} / 0.6745.$$

MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are p columns in X , the smallest p absolute deviations are excluded when computing the median.

Default tuning constants give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

- Structure with the function handle `RobustWgtFun` and optional scalar `Tune` fields — You can specify a custom weight function. `fitlm` uses the `RobustWgtFun` weight

function and `Tune` tuning constant from the structure. Specify `RobustWgtFun` as a function handle that accepts a vector of residuals, and returns a vector of weights the same size. The fitting function scales the residuals, dividing by the tuning constant (default 1) and by an estimate of the error standard deviation before it calls the weight function.

Example: `'RobustOpts', 'andrews'`

'VarNames' — Names of variables in fit

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | cell array of character vectors

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of character vectors including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: `cell`

'Weights' — Observation weights

`ones(n, 1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: `single` | `double`

Output Arguments

mdl — Linear model

`LinearModel` object

Linear model representing a least-squares fit of the response to the data, returned as a `LinearModel` object.

If the value of the 'RobustOpts' name-value pair is not [] or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

For properties and methods of the linear model object, mdl, see the LinearModel class page.

Definitions

Terms Matrix

A terms matrix is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and plus one is for the response variable.

The value of $T(i, j)$ is the exponent of variable j in term i . Suppose there are three predictor variables A, B, and C:

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
dsa = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0 0 0 0
1 0 0 0
0 0 1 0
0 0 0 1

```

Redefine the dataset array.

```

dsa = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker, 'VarNames',{ 'BloodPressure', 'Sex', 'Age', 'Smoker' });

```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

T =

```

0 0 0 0
0 1 0 0
0 0 1 0
0 0 0 1

```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```

load carsmall
X = [Acceleration,Weight];

```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

T =

```

0 0 0
1 0 0
0 1 0

```

```

1    1    0
0    2    0

```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

```
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the `Weight` variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
```

```
mdl = stepwiselm(X,MPG,[0 0 0], 'upper', T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

```
mdl =
```

Linear regression model:

```
y ~ 1 + x2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49

```
x2          -0.0086119    0.0005348    -16.103    1.6434e-28
```

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

Formula

A formula for model specification is a character vector of the form `'Y ~ terms'`

where

- `Y` is the response name.
- `terms` contains
 - Variable names
 - `+` means include the next variable
 - `-` means do not include the next variable
 - `:` defines an interaction, a product of terms
 - `*` defines an interaction **and all lower-order terms**
 - `^` raises the predictor to a power, exactly as in `*` repeated, so `^` includes lower order terms as well
 - `()` groups terms

Note: Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include `-1` in the formula.

For example,

`'Y ~ A + B + C'` means a three-variable linear model with intercept.

`'Y ~ A + B + C - 1'` is a three-variable linear model without intercept.

`'Y ~ A + B + C + B^2'` is a three-variable model with intercept and a `B^2` term.

`'Y ~ A + B^2 + C'` is the same as the previous example because `B^2` includes a `B` term.

' $Y \sim A + B + C + A:B$ ' includes an $A*B$ term.

' $Y \sim A*B + C$ ' is the same as the previous example because $A*B = A + B + A:B$.

' $Y \sim A*B*C - A:B:C$ ' has all interactions among A, B, and C, except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of A with each of the other variables.

Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	A, B, $A*B$
$A:B$	$A*B$ only
-B	Do not include B
$A*B + C$	A, B, C, $A*B$
$A + B + C + A:B$	A, B, C, $A*B$
$A*B*C - A:B:C$	A, B, C, $A*B$, $A*C$, $B*C$
$A*(B + C)$	A, B, C, $A*B$, $A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Tall Arrays

This function supports tall arrays for out-of-memory data with some limitations.

- If any input argument to `fitlm` is a tall array, then all of the other inputs must be tall arrays as well. This includes nonempty variables supplied with the `'Weights'` and `'Exclude'` name-value pairs.
- The `'RobustOpts'` name-value pair is not supported with tall arrays.
- For tall data, `fitlm` returns a `CompactLinearModel` object that contains most of the same properties as a `LinearModel` object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these `LinearModel` properties:
 - `Diagnostics`
 - `Fitted`
 - `ObservationInfo`
 - `ObservationNames`
 - `Residuals`
 - `Steps`
 - `Variables`

You can compute the residuals directly from the compact object returned by `LM = fitlm(X,Y)` using

```
RES = Y - predict(LM,X);  
S = LM.RMSE;  
histogram(RES,linspace(-3*S,3*S,51))
```

- If the `CompactLinearModel` object is missing lower order terms that include categorical factors:
 - The `plotEffects` and `plotInteraction` methods are not supported.
 - The `anova` method with the `'components'` option is not supported.

For more information, see “Tall Arrays” (MATLAB).

fitlme

Fit linear mixed-effects model

Syntax

```
lme = fitlme(tbl,formula)
lme = fitlme(tbl,formula,Name,Value)
```

Description

`lme = fitlme(tbl,formula)` returns a linear mixed-effects model, specified by `formula`, fitted to the variables in the table or dataset array `tbl`.

`lme = fitlme(tbl,formula,Name,Value)` returns a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

Examples

Fit Linear Mixed-Effects Model

Load the sample data.

```
load imports-85
```

Store the variables in a table.

```
tbl = table(X(:,12),X(:,14),X(:,24),'VariableNames',{'Horsepower','CityMPG','EngineType'})
```

Display the first five rows of the table.

```
tbl(1:5,:)
```

```
ans =
```

```
5×3 table
```

Horsepower	CityMPG	EngineType
111	21	13
111	21	13
154	19	37
102	24	35
115	18	35

Fit a linear mixed-effects model for miles per gallon in the city, with fixed effects for horsepower, and uncorrelated random effect for intercept and horsepower grouped by the engine type.

```
lme = fitlme(tbl, 'CityMPG~Horsepower+(1|EngineType)+(Horsepower-1|EngineType)');
```

In this model, `CityMPG` is the response variable, `horsepower` is the predictor variable, and engine type is the grouping variable. The fixed-effects portion of the model corresponds to `1 + Horsepower`, because the intercept is included by default.

Since the random-effect terms for intercept and horsepower are uncorrelated, these terms are specified separately. Because the second random-effect term is only for horsepower, you must include a `-1` to eliminate the intercept from the second random-effect term.

Display the model.

```
lme
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	203
Fixed effects coefficients	2
Random effects coefficients	14
Covariance parameters	3

```
Formula:
```

```
CityMPG ~ 1 + Horsepower + (1 | EngineType) + (Horsepower | EngineType)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
1099.5	1116	-544.73	1089.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	37.276	2.8556	13.054	201	1.3147e-28
'Horsepower'	-0.12631	0.02284	-5.53	201	9.8848e-08

Lower	Upper
31.645	42.906
-0.17134	-0.081269

Random effects covariance parameters (95% CIs):

Group: EngineType (7 Levels)

Name1	Name2	Type	Estimate	Lower
'(Intercept)'	'(Intercept)'	'std'	5.7338	2.3773

Upper
13.829

Group: EngineType (7 Levels)

Name1	Name2	Type	Estimate	Lower
'Horsepower'	'Horsepower'	'std'	0.050357	0.02307

Upper
0.10992

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.226	2.9078	3.5789

Note that the random-effects covariance parameters for intercept and horsepower are separate in the display.

Now, fit a linear mixed-effects model for miles per gallon in the city, with the same fixed-effects term and potentially correlated random effect for intercept and horsepower grouped by the engine type.

```
lme2 = fitlme(tbl, 'CityMPG~Horsepower+(Horsepower|EngineType)');
```

Because the random-effect term includes the intercept by default, you do not have to add 1, the random effect term is equivalent to (1 + Horsepower | EngineType).

Display the model.

```
lme2
```

```
lme2 =
```

  Name          Estimate    Lower    Upper
  'Res Std'     3.1845    2.8774   3.5243

```

Note that the random effects covariance parameters for intercept and horsepower are together in the display, and it includes the correlation ('corr') between the intercept and horsepower.

Fit Random Intercept LME Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the new response variable `FluRate`, the nominal variable `Region` that shows which region each estimate is from, the nationwide estimate `WtdILI`, and the grouping variable `Date`.

```

flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);

```

Display the first six rows of `flu2`.

```
flu2(1:6,:)
```

```
ans =
```

```

    Date      WtdILI    Region    FluRate
    10/9/2005    1.182     NE         0.97
    10/9/2005    1.182   MidAtl     1.025
    10/9/2005    1.182  ENCentral  1.232

```

10/9/2005	1.182	WNCentral	1.286
10/9/2005	1.182	SATl	1.082
10/9/2005	1.182	ESCentral	1.457

Fit a linear mixed-effects model with a fixed-effects term for the nationwide estimate, `WtdILI`, and a random intercept that varies by `Date`. The model corresponds to

$$y_{im} = \beta_0 + \beta_1 \text{WtdILI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i . The random effect has the prior distribution,

$$b_{0m} \sim N(0, \sigma_b^2),$$

and the error term has the distribution,

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
lme = fitlme(flu2, 'FluRate ~ 1 + WtdILI + (1|Date)')
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```

Random effects covariance parameters (95% CIs):
Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower
'(Intercept)'	'(Intercept)'	'std'	0.17146	0.13227
				Upper
				0.22226

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

Estimated covariance parameters are displayed in the section titled "Random effects covariance parameters". The estimated value of σ_b is 0.17146 and its 95% confidence interval is [0.13227, 0.22226]. Since this interval does not include 0, the random-effects term is significant. You can formally test the significance of any random-effects term using a likelihood ratio test via the `compare` (`LinearMixedModel`) method.

The estimated response at an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the estimated best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')

y_hat =
```

```
1.4674
```

You can display the fitted value using the `fitted` method.

```
F = fitted(lme);  
F(28)
```

```
ans =
```

```
1.4674
```

LME Model for Randomized Block Design

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'))
```

The data shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift. Use the restricted maximum likelihood method and `'effects'` contrasts.

`'effects'` contrasts mean that the coefficients sum to 0, and `fitlme` creates a matrix called a *fixed effects design matrix* to describe the effect of shift. This matrix has two columns, `Shift_Evening` and `Shift_Morning`, where

$$\text{Shift_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

$$\text{Shift_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

The model corresponds to

$$\begin{aligned} \text{Morning Shift: } \text{QCDev}_{im} &= \beta_0 + \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im}, \\ \text{Evening Shift: } \text{QCDev}_{im} &= \beta_0 + \beta_1 \text{Shift_Evening}_i + b_{0m} + \epsilon_{im}, \\ \text{Night Shift: } \text{QCDev}_{im} &= \beta_0 - \beta_1 \text{Shift_Evening}_i - \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im}, \end{aligned}$$

where i represents the observations, and m represents the operators, $i = 1, 2, \dots, 15$, and $m = 1, 2, \dots, 5$. The random effects and the observation error have the following distributions:

$$b_{0m} \sim N(0, \sigma_b^2)$$

and

$$\epsilon_{im} \sim N(0, \sigma^2).$$

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)', ...
'FitMethod', 'REML', 'DummyVarCoding', 'effects')
```

```
lme =
```

```
Linear mixed-effects model fit by REML

Name	Estimate	Lower	Upper
'Res Std'	0.85462	0.52357	1.395

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

```
B = randomEffects(lme)
```

```
B =
```

```

 0.5775
 1.1757
-2.1715
 2.3655
-1.9472

```

The estimated absolute deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}
 \hat{y}_{\text{Evening Operator}_3} &= \hat{\beta}_0 + \hat{\beta}_1 \text{Shift_Evening} + \hat{b}_{03} \\
 &= 3.6525 - 0.53293 - 2.1715 \\
 &= 0.94807.
 \end{aligned}$$

You can also display this value as follows.

```

F = fitted(lme);
F(Shift.Shift=='Evening' & shift.Operator=='3')

```

```
ans =
    0.9481
```

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working the morning shift as

$$\begin{aligned}\hat{y}_{\text{Morning,Operator}_3} &= \hat{\beta}_0 + \hat{\beta}_2 \text{Shift_Morning} + \hat{b}_{03} \\ &= 3.6525 - 0.91973 - 2.1715 \\ &= 0.56127.\end{aligned}$$

You can also display this value as follows.

```
F(shift.Shift=='Morning' & shift.Operator=='3')
```

```
ans =
    0.5613
```

The operator tends to make a smaller magnitude of error during the morning shift.

LME Model for Split-Plot Experiment

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'))
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

$$y_{imjk} = \beta_0 + \sum_{m=2}^4 \beta_{1m} I[F]_{im} + \sum_{j=2}^5 \beta_{2j} I[T]_{ij} + \sum_{j=2}^5 \sum_{m=2}^4 \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S * T)_{jk} + \varepsilon_{imjk},$$

where $i = 1, 2, \dots, 60$, index m corresponds to the fertilizer types, j corresponds to the tomato types, and $k = 1, 2, 3$ corresponds to the blocks (soil). S_k represents the k th soil type, and $(S * T)_{jk}$ represents the j th tomato type nested in the k th soil type. $I[F]_{im}$ is the dummy variable representing level m of the fertilizer. Similarly, $I[T]_{ij}$ is the dummy variable representing level j of the tomato type.

The random effects and observation error have these prior distributions: $b_{0k} \sim N(0, \sigma_S^2)$, $b_{0jk} \sim N(0, \sigma_{S*T}^2)$, and $\varepsilon_{imjk} \sim N(0, \sigma^2)$.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)')
```

```
lme =
```

Linear mixed-effects model fit by ML

The *P*-values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the `anova` (`LinearMixedModel`) method after refitting the model using `'effects'` contrasts.

The confidence interval for the standard deviations of the random-effects terms (σ_s^2), where the intercept is grouped by soil, is very large. This term does not appear significant.

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term `(1 | Soil)`.

```
lme = fitlme(ds, 'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)')
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

You can compare the two models using the `compare (LinearMixedModel)` method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term are tested.

Longitudinal Study with a Covariate

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'))
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`fitlme` uses program A as a reference and creates the necessary dummy variables $I[\cdot]$. Since the model already has an intercept, `fitlme` only creates dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\ + \beta_6 (\text{Week}_i * I[\text{PB}]_i) + \beta_7 (\text{Week}_i * I[\text{PC}]_i) + \beta_8 (\text{Week}_i * I[\text{PD}]_i) \\ + b_{0m} + b_{1m} \text{Week}_{im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. `IW` stands for initial weight and $I[\cdot]$ is a

dummy variable representing a type of program. For example, $I[\text{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)')
```

```
lme =

The *P*-values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-58). You must specify the model for the variables using `formula`.

Data Types: `single` | `double` | `char` | `cell`

formula — Formula for model specification

character vector of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a character vector of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. The formula is case sensitive. For a full description, see “Formula” on page 29-2257.

Example: `'y ~ treatment + (1|block)'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

`'CovariancePattern', 'Diagonal', 'Optimizer', 'fminunc', 'OptimizerOptions', opt` specifies a model, where the random-effects terms have a diagonal covariance matrix structure, and `fitlme` uses the `fminunc` optimization algorithm with the custom optimization parameters defined in variable `opt`.

'CovariancePattern' — Pattern of covariance matrix

`'FullCholesky'` (default) | character vector | square symmetric logical matrix | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of `'CovariancePattern'` and a character vector, a square symmetric logical matrix, or a cell array of character vectors or logical matrices.

If there are R random-effects terms, then the value of `'CovariancePattern'` must be a cell array of length R , where each element r of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

`'CompSymm'`

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

`PAT`

Square symmetric logical matrix. If `'CovariancePattern'` is defined by the matrix `PAT`, and if `PAT(a,b) = false`, then the `(a,b)` element of the corresponding covariance matrix is constrained to be 0.

Example: `'CovariancePattern','Diagonal'`

Example: `'CovariancePattern',{'Full','Diagonal'}`

'FitMethod' — Method for estimating parameters

`'ML'` (default) | `'REML'`

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of `'FitMethod'` and either of the following.

`'ML'`

Default. Maximum likelihood estimation

`'REML'`

Restricted maximum likelihood estimation

Example: `'FitMethod','REML'`

'Weights' — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n , where n is the number of observations.

Data Types: `single` | `double`**'Exclude' — Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude', [13,67]`Data Types: `single` | `double` | `logical`**'DummyVarCoding' — Coding to use for dummy variables**`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the following.

Value	Description
<code>'reference'</code>	Default. Coefficient for first category set to 0.
<code>'effects'</code>	Coefficients sum to 0.
<code>'full'</code>	One dummy variable for each category.

Example: `'DummyVarCoding', 'effects'`**'Optimizer' — Optimization algorithm**`'quasnewton'` (default) | `'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

'quasinevton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminunc'

'OptimizerOptions' — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasinevton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasinevton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

'ToIFun' — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

'ToIX' — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

'MaxIter' — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

'Display' — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

'StartMethod' — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

Value	Description
'default'	An internally defined default value
'random'	A random initial value

Example: 'StartMethod', 'random'

'Verbose' — Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose', true

'CheckHessian' — Indicator to check positive definiteness of Hessian`false (default) | true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either `false` or `true`. Default is `false`.

Specify 'CheckHessian' as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian', `true`

Output Arguments

lme — Linear mixed-effects model`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

Definitions

Formula

In general, a formula for model specification is a character vector of the form '`y ~ terms`'. For the linear mixed-effects models, this formula is in the form '`y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)`', where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, `Xj`, which can be continuous or grouping variables
- Grouping variables, `g1`, `g2`, ..., `gR`,

where the grouping variables in `Xj` and `gr` can be categorical, logical, character arrays, or cell arrays of character vectors.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR）'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix X , `random1` is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1 , and similarly `randomR` is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R . You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X ^k , where k is a positive integer	X, X ² , ..., X ^k
X1 + X2	X1, X2
X1*X2	X1, X2, X1.*X2 (elementwise multiplication of X1 and X2)
X1:X2	X1.*X2 only
- X2	Do not include X2
X1*X2 + X3	X1, X2, X3, X1*X2
X1 + X2 + X3 + X1:X2	X1, X2, X3, X1*X2
X1*X2*X3 - X1:X2:X3	X1, X2, X3, X1*X2, X1*X3, X2*X3
X1*(X2 + X3)	X1, X2, X3, X1*X2, X1*X3

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
<code>'y ~ X1 + X2'</code>	Fixed effects for the intercept, X1 and X2. This is equivalent to <code>'y ~ 1 + X1 + X2'</code> .
<code>'y ~ -1 + X1 + X2'</code>	No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including <code>-1</code> .

Formula	Description
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Alternatives

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

LinearMixedModel | `fitlmematrix`

Introduced in R2013b

fitlmematrix

Fit linear mixed-effects model

Syntax

```
lme = fitlmematrix(X,y,Z,[])  
lme = fitlmematrix(X,y,Z,G)  
lme = fitlmematrix( ____,Name,Value)
```

Description

`lme = fitlmematrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where n is the number of observations. Using `fitlmematrix(X,Y,Z,[])` without a specified covariance pattern most likely results in a nonidentifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using the 'CovariancePattern' name-value pair argument.

`lme = fitlmematrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = fitlmematrix(____,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

Examples

No Grouping Variable Specified

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, where miles per gallon (MPG) is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```
y = MPG;
X = [ones(size(Weight)), Weight];
Z = ones(size(y));
lme = fitlmematrix(X,y,Z,Model_Year)
```

```
lme =
```

```

Longitudinal Study with a Covariate

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\ + \beta_6 (\text{Week}_i * I[\text{PB}]_i) + \beta_7 (\text{Week}_i * I[\text{PC}]_i) + \beta_8 (\text{Week}_i * I[\text{PD}]_i) \\ + b_{0m} + b_{1m} \text{Week}_{im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. `IW` stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[\text{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```

Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
X = [ones(120,1), InitialWeight, D(:,2:4), Week,...
     D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;

```

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```

lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Week_PrgC','Week_PrgD',
'RandomEffectPredictors',{{'Intercept','Week'}},'RandomEffectGroups',{'Subject'})

```

```
lme =
```

Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

Examine the fixed effects coefficients table. The row labeled 'InitWeight' has a *P*-value of 0.0228, and the row labeled 'Week' has a *P*-value of 0.0115. These *P*-values indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus

they seem significant. You can also test the significance of the random-effects using the `compare` method.

Random Intercept Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into an array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...  
            'IndVarName','Region');  
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by `Date`. The corresponding model is

$$y_{im} = \beta_0 + \beta_1 \text{WtdILI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i . The random effect has the prior distribution,

$$b_{0m} \sim N(0, \sigma_b^2),$$

and the error term has the distribution,

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
y = flu2.FluRate;  
X = [ones(468,1) flu2.WtdILI];  
Z = [ones(468,1)];  
G = flu2.Date;
```

Fit the linear mixed-effects model.

```
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',{'Intercept','NationalRate'},...
'RandomEffectPredictors',{'Intercept'}), 'RandomEffectGroups',{'Date'})
```

lme =

Linear mixed-effects model fit by ML

Model information:

Lower	Upper				
0.050813	0.27689				
0.66028	0.78691				

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower
'Intercept'	'Intercept'	'std'	0.17146	0.13227

Upper
0.22226

Group: Error

Name	Estimate	Lower	Upper
------	----------	-------	-------

```
'Res Std'          0.30201      0.28217      0.32324
```

The confidence limits of the standard deviation of the random-effects term σ_b , do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using `compare` method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics STATS
STATS.Level = nominal(STATS.Level1);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
```

```
y_hat =
    1.4674
```

You can simply display the fitted value using the `fitted(lme)` method.

```
F = fitted(lme);
F(28)
```

```
ans =
    1.4674
```

Randomized Block Design

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'));
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. 'effects' contrasts mean that the coefficients sum to 0. You need to create two contrast coded variables in the fixed-effects design matrix, X1 and X2, where

$$\text{Shift_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

$$\text{Shift_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

The model corresponds to

$$\begin{aligned} \text{Morning Shift:} \quad \text{QCDev}_{im} &= \beta_0 + \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im}, \\ \text{Evening Shift:} \quad \text{QCDev}_{im} &= \beta_0 + \beta_1 \text{Shift_Evening}_i + b_{0m} + \epsilon_{im}, \\ \text{Night Shift:} \quad \text{QCDev}_{im} &= \beta_0 - \beta_1 \text{Shift_Evening}_i - \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im}, \end{aligned}$$

where i represents the observations, and m represents the operators, $i = 1, 2, \dots, 15$, and $m = 1, 2, \dots, 5$. The random effects and the observation error have the following distributions:

$$b_{0m} \sim N(0, \sigma_b^2)$$

and

$$\epsilon_{im} \sim N(0, \sigma^2).$$

```
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
```

```

y = shift.QCDev;
Z = ones(15,1);
G = shift.Operator;

```

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

```

lme = fitlmematrix(X,y,Z,G,'FitMethod','REML','FixedEffectPredictors',...
{'Intercept','S_Morning','S_Evening'},'RandomEffectPredictors',{{'Intercept'}},...
'RandomEffectGroups',{'Operator'},'DummyVarCoding','effects')

```

```

The estimated deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}\hat{y}_{\text{Evening Operator}_3} &= \hat{\beta}_0 + \hat{\beta}_1 \text{Shift_Evening} + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans =
```

```
0.9481
```

Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and uncorrelated random effect for intercept and acceleration grouped by the model year. This model corresponds to

$$\text{MPG}_{im} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{HP} + b_{0m} + b_{1m} \text{Acc}_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2),$$

$$b_{1m} \sim N(0, \sigma_1^2),$$

where m represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1), Acceleration};
G = {Model_Year, Model_Year};
Model_Year = nominal(Model_Year);
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X, MPG, Z, G, 'FixedEffectPredictors', ...
    {'Intercept', 'Acceleration', 'Horsepower'}, 'RandomEffectPredictors', ...
    {{'Intercept'}, {'Acceleration'}}, 'RandomEffectGroups', {'Model_Year', 'Model_Year'})
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	3

```
Formula:
```

```
Linear Mixed Formula with 4 predictors.
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2194.5	2218.3	-1091.3	2182.5

Fixed effects coefficients (95% CIs):

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.7258	3.4698	4.0007

Note that the random effects covariance parameters for intercept and acceleration are separate in the display. The standard deviation of the random effect for the intercept does not seem significant.

Refit the model with potentially correlated random effects for intercept and acceleration. In this case, the random-effects terms has this prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where m represents the model year.

First, prepare the random-effects design matrix and grouping variable.

```
Z = [ones(406,1) Acceleration];
G = Model_Year;

lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'})
```

```
lme =

'Res Std'	3.6874	3.4298	3.9644

Note that the random effects covariance parameters for intercept and acceleration are together in the display, with an addition of the correlation between the intercept and acceleration. The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include 0s, hence they seem significant. You can compare these two models using the `compare` (`LinearMixedModel`) method.

Specify the Covariance Pattern

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables.

```
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week as the fixed effects.

```
D = dummyvar(Program);
```

```
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\ + b_{0m} + b_{1m} \text{Week}_{2im} + b_{2m} \text{Week}_{4im} + b_{3m} \text{Week}_{6im} + b_{4m} \text{Week}_{8im} \\ + b_{5m} \text{Week}_{10im} + b_{6m} \text{Week}_{12im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$.

β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[\text{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```
lme = fitlmematrix(X,y,Z,G, 'FixedEffectPredictors',...
{'Intercept', 'InitWeight', 'PrgB', 'PrgC', 'PrgD', 'Week'},...
'RandomEffectPredictors', {'Intercept', 'Week'},...
'RandomEffectGroups', {'Subject'}, 'CovariancePattern', 'Isotropic')
```

```
lme =

Input Arguments

X — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of **X** corresponds to one observation, and each column of **X** corresponds to one variable.

Data Types: `single` | `double`

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then **Z** must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then **Z** must be a cell array of length *R*. Each cell of **Z** contains an *n*-by-*q*(*r*) design matrix $Z\{r\}$, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, $Z\{r\}$.

Data Types: `single` | `double` | `cell`

G — Grouping variable or variables

n-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then **G** must be an *n*-by-1 vector corresponding to a single grouping variable with *M* levels or groups.

G can be a categorical vector, numeric vector, character array, or cell array of character vectors.

- If there are multiple random-effects terms, then **G** must be a cell array of length *R*. Each cell of **G** contains a grouping variable **G{r}**, $r = 1, 2, \dots, R$, with $M(r)$ levels.

G{r} can be a categorical vector, numeric vector, character array, or cell array of character vectors.

Data Types: `single` | `double` | `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example:

`'CovariancePattern', 'Diagonal', 'DummyVarCoding', 'full', 'Optimizer', 'fminunc'` specifies a random-effects covariance pattern with zero off-diagonal elements, creates a dummy variable for each level of a categorical variable, and uses the `fminunc` optimization algorithm.

'FixedEffectPredictors' — Names of columns in fixed-effects design matrix
`{'x1', 'x2', ..., 'xP'}` (default) | cell array of length *p*

Names of columns in the fixed-effects design matrix **X**, specified as the comma-separated pair consisting of **'FixedEffectPredictors'** and a cell array of length *p*.

For example, if you have a constant term and two predictors, say **TimeSpent** and **Gender**, where **Female** is the reference level for **Gender**, as the fixed effects, then you can specify the names of your fixed effects in the following way. **Gender_Male** represents the dummy variable you must create for category **Male**. You can choose different names for these variables.

Example: `'FixedEffectPredictors',`
`{'Intercept', 'TimeSpent', 'Gender_Male'},`

Data Types: `cell`

'RandomEffectPredictors' — Names of columns in random-effects design matrix or cell array

cell array of length q | cell array of length R with elements of length $q(r)$, $r = 1, 2, \dots, R$

Names of columns in the random-effects design matrix or cell array Z , specified as the comma-separated pair consisting of `'RandomEffectPredictors'` and either of the following:

- A cell array of length q when Z is an n -by- q design matrix. In this case, the default is `{'z1', 'z2', ..., 'zQ'}`.
- A cell array of length R , when Z is a cell array of length R with each element $Z\{r\}$ of length $q(r)$, $r = 1, 2, \dots, R$. In this case, the default is `{'z11', 'z12', ..., 'z1Q(1)', ..., {'zr1', 'zr2', ..., 'zrQ(r)'}}`.

For example, suppose you have correlated random effects for intercept and a variable named `Acceleration`. Then, you can specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {'Intercept', 'Acceleration'}`

If you have two random effects terms, one for the intercept and the variable `Acceleration` grouped by variable `g1`, and the second for the intercept, grouped by the variable `g2`, then you specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {'Intercept', 'Acceleration'}, {'Intercept'}`

Data Types: `cell`

'ResponseVarName' — Name of response variable

`'y'` (default) | character vector

Name of response variable, specified as the comma-separated pair consisting of `'ResponseVarName'` and a character vector.

For example, if your response variable name is `score`, then you can specify it as follows.

Example: `'ResponseVarName', 'score'`

Data Types: `char`

'RandomEffectGroups' — Names of random effects grouping variables

`'g'` or `{'g1', 'g2', ..., 'gR'}` (default) | character vector | cell array of character vectors

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:

- Character vector — If there is only one random-effects term, that is, if G is a vector, then the value of 'RandomEffectGroups' is a character vector containing the name for the grouping variable G . The default is 'g'.
- Cell array of character vectors — If there are multiple random-effects terms, that is, if G is a cell array of length R , then the value of 'RandomEffectGroups' is a cell array of length R , where each cell contains the name for the grouping variable $G\{r\}$. The default is {'g1', 'g2', ..., 'gR'}.

For example, if you have two random-effects terms, $z1$ and $z2$, grouped by the grouping variables `sex` and `subject`, then you can specify the names of your grouping variables as follows.

Example: 'RandomEffectGroups', {'sex', 'subject'}

Data Types: char | cell

'CovariancePattern' — Pattern of covariance matrix

'FullCholesky' (default) | character vector | square symmetric logical matrix | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a character vector, a square symmetric logical matrix, or a cell array of character vectors or logical matrices.

If there are R random-effects terms, then the value of 'CovariancePattern' must be a cell array of length R , where each element r of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

`'CompSymm'`

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

`PAT`

Square symmetric logical matrix. If `'CovariancePattern'` is defined by the matrix `PAT`, and if `PAT(a,b) = false`, then the `(a,b)` element of the corresponding covariance matrix is constrained to be 0.

Example: `'CovariancePattern', 'Diagonal'`

Example: `'CovariancePattern', {'Full', 'Diagonal'}`

'FitMethod' — Method for estimating parameters

`'ML'` (default) | `'REML'`

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of `'FitMethod'` and either of the following.

`'ML'`

Default. Maximum likelihood estimation

`'REML'`

Restricted maximum likelihood estimation

Example: `'FitMethod', 'REML'`

'Weights' — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n , where n is the number of observations.

Data Types: `single` | `double`**'Exclude' — Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude', [13,67]`Data Types: `single` | `double` | `logical`**'DummyVarCoding' — Coding to use for dummy variables**`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the following.

Value	Description
<code>'reference'</code>	Default. Coefficient for first category set to 0.
<code>'effects'</code>	Coefficients sum to 0.
<code>'full'</code>	One dummy variable for each category.

Example: `'DummyVarCoding', 'effects'`**'Optimizer' — Optimization algorithm**`'quasnewton'` (default) | `'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

'quasinevton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminunc'

'OptimizerOptions' — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasinevton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasinevton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

'ToIFun' — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

'ToIX' — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

'MaxIter' — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

'Display' — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

'StartMethod' — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

Value	Description
'default'	An internally defined default value
'random'	A random initial value

Example: 'StartMethod', 'random'

'Verbose' — Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: `'Verbose', true`

'CheckHessian' — Indicator to check positive definiteness of Hessian

`false` (default) | `true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of `'CheckHessian'` and either `false` or `true`. Default is `false`.

Specify `'CheckHessian'` as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: `'CheckHessian', true`

Output Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

Definitions

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Alternative Functionality

You can also fit a linear mixed-effects model using `fitlme(tbl, formula)`, where `tbl` is a table or dataset array containing the response `y`, the predictor variables `X`, and the grouping variables, and `formula` is of the form `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`.

Introduced in R2013b

fitrgp

Fit a Gaussian process regression (GPR) model

Syntax

```
gprMdl = fitrgp(tbl,ResponseVarName)
gprMdl = fitrgp(tbl,formula)
gprMdl = fitrgp(tbl,y)
```

```
gprMdl = fitrgp(X,y)
```

```
gprMdl = fitrgp( ____,Name,Value)
```

Description

`gprMdl = fitrgp(tbl,ResponseVarName)` returns a Gaussian process regression (GPR) model trained using the sample data in `tbl`, where `ResponseVarName` is the name of the response variable in `tbl`.

`gprMdl = fitrgp(tbl,formula)` returns a Gaussian process regression (GPR) model, trained using the sample data in `tbl`, for the predictor variables and response variables identified by `formula`.

`gprMdl = fitrgp(tbl,y)` returns a GPR model for the predictors in table `tbl` and continuous response vector `y`.

`gprMdl = fitrgp(X,y)` returns a GPR model for predictors `X` and continuous response vector `y`.

`gprMdl = fitrgp(____,Name,Value)` returns a GPR model for any of the input arguments in the previous syntaxes, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the fitting method, the prediction method, the covariance function, or the active set selection method. You can also train a cross-validated model.

`gprMdl` is a `RegressionGP` object. For methods and properties of this class, see `RegressionGP` class page.

If you train a cross-validated model, then `gprMdl` is a `RegressionPartitionedModel` object. For further analysis on the cross-validated object, use the methods of `RegressionPartitionedModel` class. For the methods of this class, see the `RegressionPartitionedModel` class page.

Examples

Train GPR Model Using Data in Table

This example uses the abalone data [1], [2], from the UCI Machine Learning Repository [3]. Download the data and save it in your current folder with the name 'abalone.data'.

Store the data into a `table`. Display the first seven rows.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);tbl.Properties
tbl(1:7,:)

```

```
ans =
```

Sex	Length	Diameter	Height	WWeight	SWeight	VWeight	ShWeight
'M'	0.455	0.365	0.095	0.514	0.2245	0.101	0.15
'M'	0.35	0.265	0.09	0.2255	0.0995	0.0485	0.07
'F'	0.53	0.42	0.135	0.677	0.2565	0.1415	0.21
'M'	0.44	0.365	0.125	0.516	0.2155	0.114	0.155
'I'	0.33	0.255	0.08	0.205	0.0895	0.0395	0.055
'I'	0.425	0.3	0.095	0.3515	0.141	0.0775	0.12
'F'	0.53	0.415	0.15	0.7775	0.237	0.1415	0.33

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, number of shell rings shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Fit a GPR model using the `subset of regressors` method for parameter estimation and `fully independent conditional` method for prediction. Standardize the predictors.

```
gprMdl = fitrgp(tbl,'NoShellRings','KernelFunction','ardsquaredexponential',...  
              'FitMethod','sr','PredictMethod','fic','Standardize',1)
```

```
grMdl =
```

```
RegressionGP

  BCDInformation: []
```

Predict the responses using the trained model.

```
ypred = resubPredict(gprMdl);
```

Plot the true response and the predicted responses.

```
figure();  
plot(tbl.NoShellRings,'r.');
```

```
hold on  
plot(ypred,'b');
```

```
xlabel('x');  
ylabel('y');  
legend({'data','predictions'},'Location','Best');
```

```
axis([0 4300 0 30]);  
hold off;
```

Compute the regression loss on the training data (resubstitution loss) for the trained model.

```
L = resubLoss(gprMd1)
```

```
L =
```

```
4.0064
```

Train GPR Model and Plot Predictions

Generate sample data.

```
rng(0,'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*5e-2 + sin(x)./x + 0.2*randn(n,1);
```

Fit a GPR model using a linear basis function and the exact fitting method to estimate the parameters. Also use the exact prediction method.

```
gprMdl = fitrgp(x,y,'Basis','linear',...  
              'FitMethod','exact','PredictMethod','exact');
```

Predict the response corresponding to the rows of x (resubstitution predictions) using the trained model.

```
ypred = resubPredict(gprMdl);
```

Plot the true response with the predicted values.

```
plot(x,y,'b. ');  
hold on;  
plot(x,ypred,'r','LineWidth',1.5);  
xlabel('x');  
ylabel('y');  
legend('Data','GPR predictions');  
hold off
```

Impact of Specifying Initial Kernel Parameter Values

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'gprdata2.mat'))
```

The data has one predictor variable and continuous response. This is simulated data.

Fit a GPR model using the squared exponential kernel function with default kernel parameters.

```
gprMd11 = fitrgp(x,y, 'KernelFunction', 'squareexponential');
```

Now, fit a second model, where you specify the initial values for the kernel parameters.

```
sigma0 = 0.2;
kparams0 = [3.5, 6.2];
gprMdl2 = fitrgp(x,y,'KernelFunction','squareexponential',...
    'KernelParameters',kparams0,'Sigma',sigma0);
```

Compute the resubstitution predictions from both models.

```
ypred1 = resubPredict(gprMdl1);
ypred2 = resubPredict(gprMdl2);
```

Plot the response predictions from both models and the responses in training data.

```
figure();
plot(x,y,'r. ');
hold on
plot(x,ypred1,'b');
plot(x,ypred2,'g');
xlabel('x');
ylabel('y');
legend({'data','default kernel parameters',...
    'kparams0 = [3.5,6.2], sigma0 = 0.2'},...
    'Location','Best');
title('Impact of initial kernel parameter values');
hold off
```

The marginal log likelihood that `fitrgp` maximizes to estimate GPR parameters has multiple local solutions; the solution that it converges to depends on the initial point. Each local solution corresponds to a particular interpretation of the data. In this example, the solution with the default initial kernel parameters corresponds to a low frequency signal with high noise whereas the second solution with custom initial kernel parameters corresponds to a high frequency signal with low noise.

Use Separate Length Scales for Predictors

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'gprdata.mat'))
```

There are six continuous predictor variables. There are 500 observations in the training data set and 100 observations in the test data set. This is simulated data.

Fit a GPR model using the squared exponential kernel function with a separate length scale for each predictor. This covariance function is defined as:

$$k(x_i, x_j | \theta) = \sigma_f^2 \exp \left[-\frac{1}{2} \sum_{m=1}^d \frac{(x_{im} - x_{jm})^2}{\sigma_m^2} \right].$$

where σ_m represents the length scale for predictor m , $m = 1, 2, \dots, d$ and σ_f is the signal standard deviation. The unconstrained parametrization θ is

$$\begin{aligned} \theta_m &= \log \sigma_m, \quad \text{for } m = 1, 2, \dots, d \\ \theta_{d+1} &= \log \sigma_f. \end{aligned}$$

Initialize length scales of the kernel function at 10 and signal and noise standard deviations at the standard deviation of the response.

```
sigma0 = std(ytrain);
sigmaF0 = sigma0;
d = size(Xtrain,2);
sigmaM0 = 10*ones(d,1);
```

Fit the GPR model using the initial kernel parameter values. Standardize the predictors in the training data. Use the exact fitting and prediction methods.

```
gprMdl = fitrgp(Xtrain,ytrain,'Basis','constant','FitMethod','exact',...
'PredictMethod','exact','KernelFunction','ardsquaredexponential',...
'KernelParameters',[sigmaM0;sigmaF0],'Sigma',sigma0,'Standardize',1);
```

Compute the regression loss on the test data.

```
L = loss(gprMdl,Xtest,ytest)
```

```
L =
```

```
0.6919
```

Access the kernel information.

```
gprMdl.KernelInformation
```

```
ans =
```

```
struct with fields:
```

```
                Name: 'ARDSquaredExponential'  
    KernelParameters: [7×1 double]  
    KernelParameterNames: {7×1 cell}
```

Display the kernel parameter names.

```
gprMdl.KernelInformation.KernelParameterNames
```

```
ans =
```

```
7×1 cell array
```

```
'LengthScale1'  
'LengthScale2'  
'LengthScale3'  
'LengthScale4'  
'LengthScale5'  
'LengthScale6'  
'SigmaF'
```

Display the kernel parameters.

```
sigmaM = gprMdl.KernelInformation.KernelParameters(1:end-1,1)  
sigmaF = gprMdl.KernelInformation.KernelParameters(end)  
sigma  = gprMdl.Sigma
```

```
sigmaM =
```

```
1.0e+04 *  
  
0.0004  
0.0007
```

```
0.0004  
4.1729  
0.1018  
0.0056
```

```
sigmaF =
```

```
28.1718
```

```
sigma =
```

```
0.8162
```

Plot the log of learned length scales.

```
figure()  
plot((1:d)', log(sigmaM), 'ro-');  
xlabel('Length scale number');  
ylabel('Log of length scale');
```

The log of length scale for the 4th and 5th predictor variables are high relative to the others. These predictor variables do not seem to be as influential on the response as the other predictor variables.

Fit the GPR model without using the 4th and 5th variables as the predictor variables.

```
X = [Xtrain(:,1:3) Xtrain(:,6)];
sigma0 = std(ytrain);
sigmaF0 = sigma0;
d = size(X,2);
sigmaM0 = 10*ones(d,1);
```

```
gprMdl = fitrgp(X,ytrain,'Basis','constant','FitMethod','exact',...
'PredictMethod','exact','KernelFunction','ardsquaredexponential',...
```

```
'KernelParameters',[sigmaM0;sigmaF0],'Sigma',sigma0,'Standardize',1);
```

Compute the regression error on the test data.

```
xtest = [Xtest(:,1:3) Xtest(:,6)];  
L = loss(gprMdl,xtest,ytest)
```

```
L =
```

```
0.6928
```

The loss is similar to the one when all variables are used as predictor variables.

Compute the predicted response for the test data.

```
ypred = predict(gprMdl,xtest);
```

Plot the original response along with the fitted values.

```
figure;  
plot(ytest,'r');  
hold on;  
plot(ypred,'b');  
legend('True response','GPR predicted values','Location','Best');  
hold off
```

Optimize GPR Regression

This example shows how to optimize hyperparameters automatically using `fitrgp`. The example uses the `gprdata2` data that ships with your software.

Load the data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'gprdata2.mat'))
```

The data has one predictor variable and continuous response. This is simulated data.

Fit a GPR model using the squared exponential kernel function with default kernel parameters.

```
gprMdl1 = fitrgp(x,y, 'KernelFunction', 'squareexponential');
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng default
gprMdl2 = fitrgp(x,y,'KernelFunction','squareexponential',...
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',...
    struct('AcquisitionFunctionName','expected-improvement-plus'));
```

Iter	Eval result	Objective	Objective runtime	BestSoFar (observed)	BestSoFar (estim.)	Sigma

Optimization completed.

MaxObjectiveEvaluations of 30 reached.

Total function evaluations: 30

Total elapsed time: 134.5352 seconds.

Total objective function evaluation time: 94.4555

Best observed feasible point:

Sigma

0.16967

Observed objective function value = 0.03789

Estimated objective function value = 0.037714

Function evaluation time = 3.0948

Best estimated feasible point (according to models):

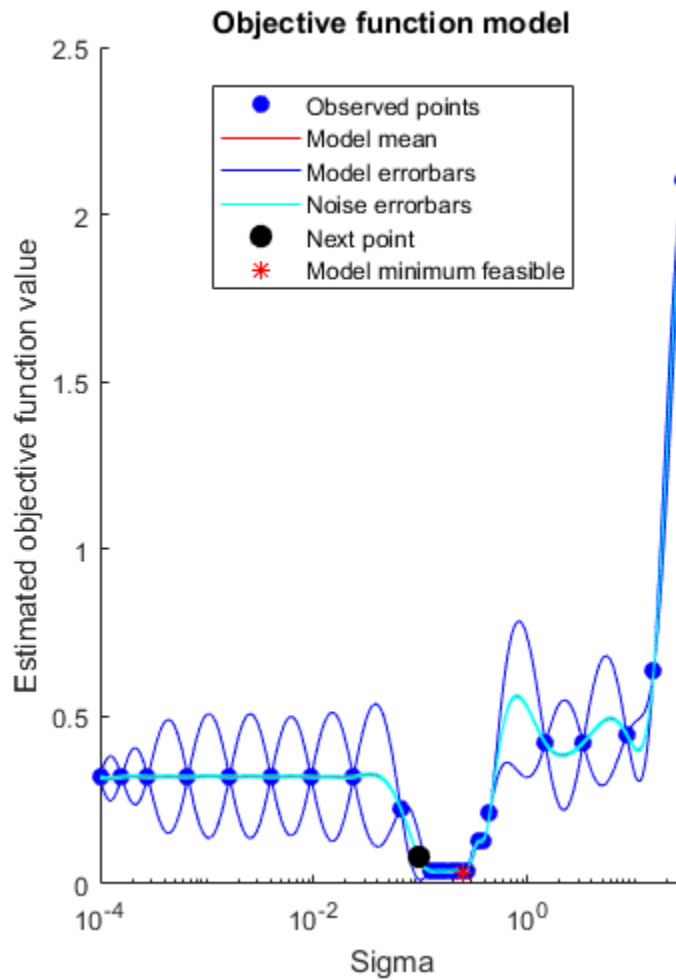

Sigma

0.22534

Estimated objective function value = 0.037714

Estimated function evaluation time = 3.0164

Compare the pre- and post-optimization fits.

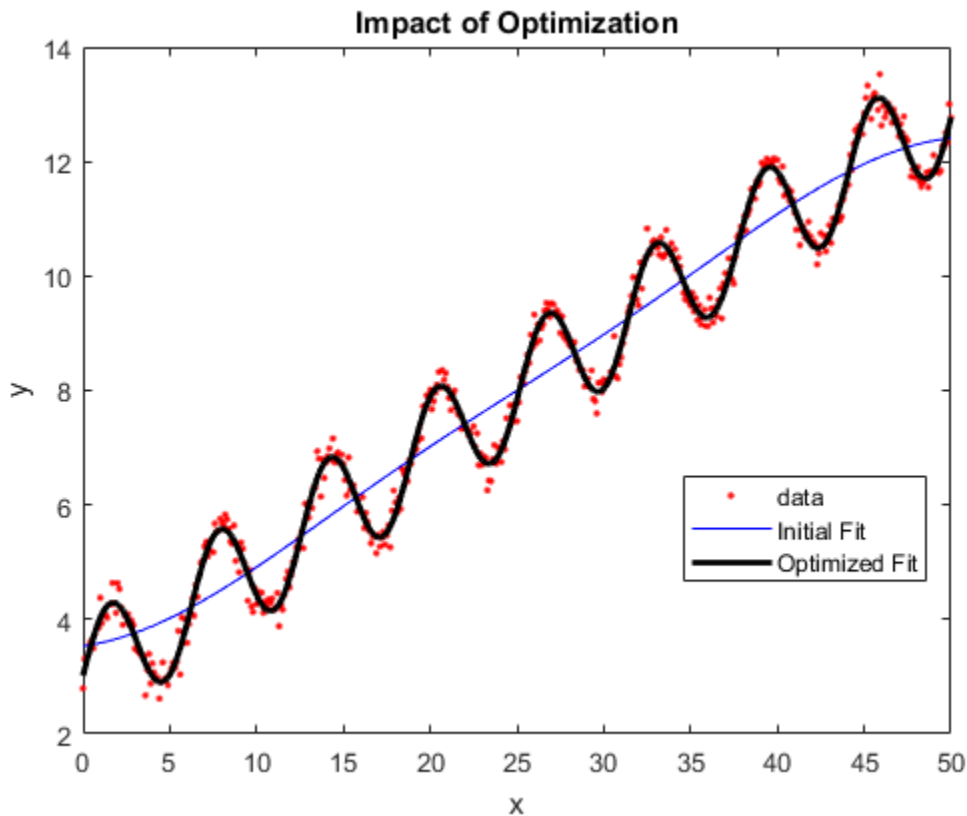

```
ypred1 = resubPredict(gprMd11);
ypred2 = resubPredict(gprMd12);
```

```
figure();
plot(x,y,'r. ');
hold on
```

```

plot(x,ypred1,'b');
plot(x,ypred2,'k','LineWidth',2);
xlabel('x');
ylabel('y');
legend({'data','Initial Fit','Optimized Fit'},'Location','Best');
title('Impact of Optimization');
hold off

```

Train GPR Model Using Cross-Validation

This example uses the abalone data [1], [2], from the UCI Machine Learning Repository [3]. Download the data and save it in your current folder with the name 'abalone.data'.

Store the data into a `table`. Display the first seven rows.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);tbl.Properties
tbl(1:7,:)
```

```
ans =
```

Sex	Length	Diameter	Height	WWeight	SWeight	VWeight	ShWeight
'M'	0.455	0.365	0.095	0.514	0.2245	0.101	0.15
'M'	0.35	0.265	0.09	0.2255	0.0995	0.0485	0.07
'F'	0.53	0.42	0.135	0.677	0.2565	0.1415	0.21
'M'	0.44	0.365	0.125	0.516	0.2155	0.114	0.155
'I'	0.33	0.255	0.08	0.205	0.0895	0.0395	0.055
'I'	0.425	0.3	0.095	0.3515	0.141	0.0775	0.12
'F'	0.53	0.415	0.15	0.7775	0.237	0.1415	0.33

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, number of shell rings shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Train a cross-validated GPR model using the 25% of the data for validation.

```
rng('default') % For reproducibility
cvgprMdl = fitrgp(tbl, 'NoShellRings', 'Standardize', 1, 'Holdout', 0.25);
```

Compute the average loss on folds using models trained on out-of-fold observations.

```
kfoldLoss(cvgprMdl)
```

```
ans =
    4.6409
```

Predict the responses for out-of-fold data.

```
ypred = kfoldPredict(cvgprMdl);
```

Plot the true responses used for testing and the predictions.

```
figure();
plot(ypred(cvgprMdl.Partition.test));
hold on;
y = table2array(tbl(:,end));
plot(y(cvgprMdl.Partition.test), 'r. ');
axis([0 1050 0 30]);
```

```
xlabel('x')  
ylabel('y')  
hold off;
```

Fit GPR Model Using Custom Kernel Function

Generate the sample data.

```
rng(0,'twister'); % For reproducibility  
n = 1000;  
x = linspace(-10,10,n)';  
y = 1 + x*5e-2 + sin(x)./x + 0.2*randn(n,1);
```

Define the squared exponential kernel function as a custom kernel function.

You can compute the squared exponential kernel function as

$$k(x_i, x_j | \theta) = \sigma_f^2 \exp\left(-\frac{1}{2} \frac{(x_i - x_j)^T (x_i - x_j)}{\sigma_l^2}\right),$$

where σ_f is the signal standard deviation, σ_l is the length scale. Both σ_f and σ_l must be greater than zero. This condition can be enforced by the unconstrained parametrization, $\sigma_l = \exp(\theta(1))$ and $\sigma_f = \exp(\theta(2))$, for some unconstrained parametrization vector θ .

Hence, you can define the squared exponential kernel function as a custom kernel function as follows:

```
kfcn = @(XN, XM, theta) (exp(theta(2))^2)*exp(-(pdist2(XN, XM).^2)/(2*exp(theta(1))^2));
```

Here `pdist2(XN, XM).^2` computes the distance matrix.

Fit a GPR model using the custom kernel function, `kfcn`. Specify the initial values of the kernel parameters (Because you use a custom kernel function, you must provide initial values for the unconstrained parametrization vector, `theta`).

```
theta0 = [1.5, 0.2];
gprMdl = fitrgp(x, y, 'KernelFunction', kfcn, 'KernelParameters', theta0);
```

`fitrgp` uses analytical derivatives to estimate parameters when using a built-in kernel function, whereas when using a custom kernel function it uses numerical derivatives.

Compute the resubstitution loss for this model.

```
L = resubLoss(gprMdl)
```

```
L =
```

```
0.0391
```

Fit the GPR model using the built-in squared exponential kernel function option. Specify the initial values of the kernel parameters (Because you use the built-in custom kernel function and specifying initial parameter values, you must provide the initial values for the signal standard deviation and length scale(s) directly).

```
sigmaL0 = exp(1.5);
sigmaF0 = exp(0.2);
gprMdl2 = fitrgp(x, y, 'KernelFunction', 'squareexponential', 'KernelParameters', [sigmaL0,
```

Compute the resubstitution loss for this model.

```
L2 = resubLoss(gprMd12)
```

```
L2 =
```

```
0.0391
```

The two loss values are the same as expected.

Input Arguments

tbl — Sample data

table

Sample data used to train the model, specified as a **table**. Each row of **tbl** corresponds to one observation, and each column corresponds to one variable. **tbl** contains the predictor variables, and optionally it can also contain one column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If **tbl** contains the response variable, and you want to use all the remaining variables as predictors, then specify the response variable using **ResponseVarName**.
- If **tbl** contains the response variable, and you want to use only a subset of the predictors in training the model, then specify the response variable and the predictor variables using **formula**.
- If **tbl** does not contain the response variable, then specify a response variable using **y**. The length of the response variable and the number of rows in **tbl** must be equal.

For more information on the **table** data type, please see **table**.

If your predictor data contains categorical variables, then the software uses full dummy coding for these variables. The software creates one dummy variable for each level of the categorical variable.

Data Types: **table**

ResponseVarName — Response variable name

name of a variable in **tbl**

Response variable name, specified as the name of a variable in `tbl`. You must specify `ResponseVarName` as a character vector. For example, if the response variable `y` is stored in `tbl` (as `tbl.y`), then specify it as `'y'`. Otherwise, the software treats all the columns of `tbl`, including `y`, as predictors when training the model.

Data Types: `double`

formula — Response and predictor variables to use in model training

Character vector in the form of `'y~x1+x2+x3'`

Response and predictor variables to use in model training, specified as a character vector in the form of `'y~x1+x2+x3'`. In this form, `y` represents the response variable; `x1`, `x2`, `x3` represent the predictor variables to use in training the model.

Use formula character vector if you want to specify a subset of variables in `tbl` as predictors to use when training the model. If you specify a formula character vector, then any variables that do not appear in `formula` are not used to train the model.

The formula does not indicate the form of the `BasisFunction`.

Example: `'PetalLength~PetalWidth+Species'` identifies the variable `PetalLength` as the response variable, and `PetalWidth` and `Species` as the predictor variables.

X — Predictor data for the GPR model

n-by-*d* matrix

Predictor data for the GPR model, specified as an *n*-by-*d* matrix. *n* is the number of observations (rows), and *d* is the number of predictors (columns).

The length of `y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `double`

y — Response data for the GPR model

n-by-1 vector

Response data for the GPR model, specified as an *n*-by-1 vector. You can omit `y` if you provide the `tbl` training data that also includes `y`. In that case, use `ResponseVarName` to identify the response variable or use `formula` to identify the response and predictor variables.

Data Types: `double` | `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note: You cannot use any cross-validation name-value pair along with `OptimizeHyperparameters`. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair.

Example:

```
'FitMethod', 'sr', 'BasisFunction', 'linear', 'ActiveSetMethod', 'sgma', 'PredictMet
```

trains the GPR model using the subset of regressors approximation method for parameter estimation, uses a linear basis function, uses sparse greedy matrix approximation for active selection, and fully independent conditional approximation method for prediction.

Fitting

'FitMethod' — Method to estimate parameters of the GPR model

'none' | 'exact' | 'sd' | 'sr' | 'fic'

Method to estimate parameters of the GPR model, specified as the comma-separated pair consisting of 'FitMethod' and one of the following.

Fit Method	Description
'none'	No estimation, use the initial parameter values as the known parameter values.
'exact'	Exact Gaussian process regression. Default if $n \leq 2000$, where n is the number of observations.
'sd'	Subset of data points approximation. Default if $n > 2000$, where n is the number of observations.

Fit Method	Description
'sr'	Subset of regressors approximation.
'fic'	Fully independent conditional approximation.

Example: 'FitMethod', 'fic'

'BasisFunction' — Explicit basis in the GPR model

'constant' (default) | 'none' | 'linear' | 'pureQuadratic' | function handle

Explicit basis in the GPR model, specified as the comma-separated pair consisting of 'BasisFunction' and one of the following. If n is the number of observations, the basis function adds the term $\mathbf{H}*\boldsymbol{\beta}$ to the model, where \mathbf{H} is the basis matrix and $\boldsymbol{\beta}$ is a p -by-1 vector of basis coefficients.

Explicit Basis	Basis Matrix
'none'	Empty matrix.
'constant'	$\mathbf{H} = \mathbf{1}$ <p>(n-by-1 vector of 1s, where n is the number of observations)</p>
'linear'	$\mathbf{H} = [\mathbf{1}, \mathbf{X}]$
'pureQuadratic'	$\mathbf{H} = [\mathbf{1}, \mathbf{X}, \mathbf{X}_2],$ <p>where</p> $\mathbf{X}_2 = \begin{bmatrix} x_{11}^2 & x_{12}^2 & \cdots & x_{1d}^2 \\ x_{21}^2 & x_{22}^2 & \cdots & x_{2d}^2 \\ \vdots & \vdots & \vdots & \vdots \\ x_{n1}^2 & x_{n2}^2 & \cdots & x_{nd}^2 \end{bmatrix}.$
Function handle	<p>Function handle, hfcn, that fitrgp calls as:</p> $\mathbf{H} = hfcn(\mathbf{X}),$

Explicit Basis	Basis Matrix
	where X is an n -by- d matrix of predictors and H is an n -by- p matrix of basis functions.

Example: 'BasisFunction', 'pureQuadratic'

Data Types: char | function_handle

'Beta' — Initial value of the coefficients

p -by-1 vector

Initial value of the coefficients for the explicit basis, specified as the comma-separated pair consisting of 'Beta' and p -by-1 vector, where p is the number of columns in the basis matrix H .

The basis matrix depends on the choice of the explicit basis function as follows (also see BasisFunction).

fitrgp uses the coefficient initial values as the known coefficient values, only when FitMethod is 'none'.

Data Types: double

'Sigma' — Initial value for the noise standard deviation of the Gaussian process model

std(y)/sqrt(2) (default) | positive scalar value

Initial value for the noise standard deviation of the Gaussian process model, specified as the comma-separated pair consisting of 'Sigma' and a positive scalar value.

Example: 'Sigma', 2

Data Types: double

'ConstantSigma' — Constant value of Sigma for the noise standard deviation of the Gaussian process model

false (default) | true

Constant value of Sigma for the noise standard deviation of the Gaussian process model, specified as a logical scalar. When ConstantSigma is true, fitrgp does not optimize the value of Sigma, but instead takes the initial value as the value throughout its computations.

Example: 'ConstantSigma', true

Data Types: logical

'SigmaLowerBound' — Lower bound on the noise standard deviation

`1e-2*std(y)` (default) | positive scalar value

Lower bound on the noise standard deviation, specified as the comma-separated pair consisting of **'SigmaLowerBound'** and a positive scalar value.

Example: `'SigmaLowerBound',0.02`

Data Types: double

'CategoricalPredictors' — List of categorical predictors

numeric vector | logical vector | `'all'` | cell array of character vectors

List of categorical predictors, specified as the comma-separated pair consisting of **'CategoricalPredictors'** and one of the following.

- A numeric vector with indices from 1 through p , where p is the number of columns in X or variables in `tbl`.
- A 1-by- p logical vector, with a `true` entry corresponding to the column of X or `tbl` that is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames` values.
- `'all'`, which means all predictors are categorical.

By default, if the predictor data is in a matrix (X), `fitrgp` assumes that none of the predictors are categorical unless specified as such using the `CategoricalPredictors` name-value pair argument. If the predictor data is in a table (`tbl`), the software assumes that a variable is categorical if it contains logical values, categorical values, or a cell array of character vectors.

Example: `'CategoricalPredictors',[false true false true false]` specifies the second and the fourth predictors as categorical.

Data Types: double | logical | cell

'Standardize' — Indicator to standardize data

`0` (`false`) (default) | logical value

Indicator to standardize data, specified as the comma-separated pair consisting of **'Standardize'** and a logical value.

If you set `'Standardize', 1`, then the software centers and scales each column of the predictor data, by the column mean and standard deviation, respectively. The software does not standardize the data contained in the dummy variable columns that it generates for categorical predictors.

Example: `'Standardize', 1`

Example: `'Standardize', true`

Data Types: `logical`

'Regularization' — Regularization standard deviation

`1e-2*std(y)` (default) | positive scalar value

Regularization standard deviation for sparse methods subset of regressors (`'sr'`) and fully independent conditional (`'fic'`), specified as the comma-separated pair consisting of `'Regularization'` and a positive scalar value.

Example: `'Regularization', 0.2`

Data Types: `double`

'ComputationMethod' — Method for computing log likelihood and gradient

`'qr'` (default) | `'v'`

Method for computing the log likelihood and gradient for parameter estimation using subset of regressors (`'sr'`) and fully independent conditional (`'fic'`) approximation methods, specified as the comma-separated pair consisting of `'ComputationMethod'` and one of the following.

- `'qr'` — Use QR factorization based approach, this option provides better accuracy.
- `'v'` — Use V-method-based approach. This option provides faster computation of log likelihood gradients.

Example: `'ComputationMethod', 'v'`

Kernel (Covariance) Function

'KernelFunction' — Form of the covariance function

`'squaredexponential'` (default) | `exponential` | `'matern32'` | `'matern52'` | `'rationalquadratic'` | `'ardsquaredexponential'` | `'ardexponential'` | `'ardmatern32'` | `'ardmatern52'` | `'ardrationalquadratic'` | function handle

Form of the covariance function, specified as the comma-separated pair consisting of 'KernelFunction' and one of the following.

Function	Description
'exponential'	Exponential kernel.
'squareexponential'	Squared exponential kernel.
'matern32'	Matern kernel with parameter 3/2.
'matern52'	Matern kernel with parameter 5/2.
'rationalquadratic'	Rational quadratic kernel.
'ardexponential'	Exponential kernel with a separate length scale per predictor.
'ardsquareexponential'	Squared exponential kernel with a separate length scale per predictor.
'ardmatern32'	Matern kernel with parameter 3/2 and a separate length scale per predictor.
'ardmatern52'	Matern kernel with parameter 5/2 and a separate length scale per predictor.
'ardrationalquadratic'	Rational quadratic kernel with a separate length scale per predictor.
Function handle	<p>A function handle that can be called like this:</p> $K_{mn} = \text{kfcn}(X_m, X_n, \theta)$ <p>where X_m is an m-by-d matrix, X_n is an n-by-d matrix and K_{mn} is an m-by-n matrix of kernel products such that $K_{mn}(i,j)$ is the kernel product between $X_m(i,:)$ and $X_n(j,:)$. θ is the r-by-1 unconstrained parameter vector for kfcn.</p>

For more information on the kernel functions, see “Kernel (Covariance) Function Options” on page 6-6.

Example: 'KernelFunction', 'matern32'

Data Types: char | function_handle

'KernelParameters' — Initial values for the kernel parameters

vector

Initial values for the kernel parameters, specified as the comma-separated pair consisting of `'KernelParameters'` and a vector. The size of the vector and the values depend on the form of the covariance function, specified by the `KernelFunction` name-value pair argument.

'KernelFunction'	'KernelParameters'
<code>'exponential'</code> or <code>'squaredexponential'</code> or <code>'matern32'</code> or <code>'matern52'</code>	2-by-1 vector <code>phi</code> , where <code>phi(1)</code> contains the length scale and <code>phi(2)</code> contains the signal standard deviation. Default initial value of the length scale parameter is the mean of standard deviations of the predictors, and the signal standard deviation is the standard deviation of the responses divided by square root of 2. That is, <code>phi = [mean(std(X));std(y)/sqrt(2)]</code>
<code>'rationalquadratic'</code>	3-by-1 vector <code>phi</code> , where <code>phi(1)</code> contains the length scale and <code>phi(2)</code> contains the rational quadratic exponent, and <code>phi(3)</code> contains the signal standard deviation. That is, <code>phi = [mean(std(X));1;std(y)/sqrt(2)]</code>
<code>'ardexponential'</code> or <code>'ardsquaredexponential'</code> or <code>'ardmatern32'</code> or <code>'ardmatern52'</code>	$(d+1)$ -by-1 vector <code>phi</code> , where <code>phi(i)</code> contains the length scale for predictor i and <code>phi(d+1)</code> contains the signal standard deviation. d is the number of predictor variables. Default initial value of the length scale parameters are the standard deviations of the predictors and the signal standard deviation is the standard deviation of the responses divided by square root of 2. That is, <code>phi = [std(X)';std(y)/sqrt(2)]</code>

'KernelFunction'	'KernelParameters'
'ardrationalquadratic'	<p>$(d+2)$-by-1 vector ϕ, where $\phi(i)$ contains the length scale for predictor i, $\phi(d+1)$ contains the rational quadratic exponent, and $\phi(d+2)$ contains signal standard deviation.</p> <p>Default initial value of the length scale parameters are the standard deviations of the predictors and the signal standard deviation is the standard deviation of the responses divided by square root of 2. Default initial value for the exponent is 1. That is,</p> $\phi = [\text{std}(X)'; 1; \text{std}(y)/\text{sqrt}(2)]$
Function handle	<p>r-by-1 vector as the initial value of the unconstrained parameter vector ϕ for the custom kernel function <code>kfcn</code>.</p> <p>When <code>KernelFunction</code> is a function handle, you must supply initial values for the kernel parameters.</p>

For more information on the kernel functions, see “Kernel (Covariance) Function Options” on page 6-6.

Example: 'KernelParameters', theta

Data Types: double

'DistanceMethod' – Method for computing inter-point distances

'fast' (default) | 'accurate'

Method for computing inter-point distances to evaluate built-in kernel functions, specified as the comma-separated pair consisting of 'DistanceMethod' and either 'fast' or 'accurate'. `fitrgp` computes $(x - y)^2$ as $x^2 + y^2 - 2 * x * y$ when you choose the `fast` option and as $(x - y)^2$ when you choose the `accurate` option.

Example: 'DistanceMethod', 'accurate'

Active Set Selection

'ActiveSet' — Observations in the active set

[] (default) | m -by-1 vector of integers ranging from 1 to n ($m \leq n$) | logical vector of length n

Observations in the active set, specified as the comma-separated pair consisting of 'ActiveSet' and an m -by-1 vector of integers ranging from 1 to n ($m \leq n$) or a logical vector of length n with at least one `true` element. n is the total number of observations in the training data.

`fitrgp` uses the observations indicated by `ActiveSet` to train the GPR model. The active set cannot have duplicate elements.

If you supply `ActiveSet`, then:

- `fitrgp` does not use `ActiveSetSize` and `ActiveSetMethod`.
- You cannot perform cross-validation on this model.

Data Types: `double` | `logical`

'ActiveSetSize' — Size of the active set for sparse methods

an integer m ($1 \leq m \leq n$)

Size of the active set for sparse methods ('sd', 'sr', 'fic'), specified as the comma-separated pair consisting of 'ActiveSetSize' and an integer m , $1 \leq m \leq n$, where n is the number of observations.

Default is $\min(1000, n)$ when `FitMethod` is 'sr' or 'fic', and $\min(2000, n)$, otherwise.

Example: 'ActiveSetSize', 100

Data Types: `double`

'ActiveSetMethod' — Active set selection method

'random' (default) | 'sgma' | 'entropy' | 'likelihood'

Active set selection method, specified as the comma-separated pair consisting of 'ActiveSetMethod' and one of the following.

Method	Description
'random'	Random selection

Method	Description
'sgma'	Sparse greedy matrix approximation
'entropy'	Differential entropy-based selection
'likelihood'	Subset of regressors log likelihood-based selection

All active set selection methods (except 'random') require the storage of an n -by- m matrix, where m is the size of the active set and n is the number of observations.

Example: 'ActiveSetMethod', 'entropy'

'RandomSearchSetSize' — Random search set size

59 (default) | integer value

Random search set size per greedy inclusion for active set selection, specified as the comma-separated pair consisting of 'RandomSearchSetSize' and an integer value.

Example: 'RandomSearchSetSize', 30

Data Types: double

'ToleranceActiveSet' — Relative tolerance for terminating active set selection

1e-06 (default) | positive scalar

Relative tolerance for terminating active set selection, specified as the comma-separated pair consisting of 'ToleranceActiveSet' and a positive scalar value.

Example: 'ToleranceActiveSet', 0.0002

Data Types: double

'NumActiveSetRepeats' — Number of repetitions

3 (default) | integer value

Number of repetitions for interleaved active set selection and parameter estimation when ActiveSetMethod is not 'random', specified as the comma-separated pair consisting of 'NumActiveSetRepeats' and an integer value.

Example: 'NumActiveSetRepeats', 5

Data Types: double

Prediction

'PredictMethod' — Method used to make predictions

'exact' | 'bcd' | 'sd' | 'sr' | 'fic'

Method used to make predictions from a Gaussian process model given the parameters, specified as the comma-separated pair consisting of 'PredictMethod' and one of the following.

Method	Description
'exact'	Exact Gaussian process regression method. Default, if $n \leq 10000$.
'bcd'	Block Coordinate Descent. Default, if $n > 10000$.
'sd'	Subset of Datapoints approximation.
'sr'	Subset of Regressors approximation.
'fic'	Fully Independent Conditional approximation.

Example: 'PredictMethod', 'bcd'

'BlockSizeBCD' — Block size

minimum of 1000 or n (default) | integer in the range from 1 to n

Block size for block coordinate descent method ('bcd'), specified as the comma-separated pair consisting of 'BlockSizeBCD' and an integer in the range from 1 to n , where n is the number of observations.

Example: 'BlockSizeBCD', 1500

Data Types: double

'NumGreedyBCD' — Number of greedy selections

minimum of 100 and BlockSizeBCD (default) | integer value in the range from 1 to BlockSizeBCD

Number of greedy selections for block coordinate descent method ('bcd'), specified as the comma-separated pair consisting of 'NumGreedyBCD' and an integer in the range from 1 to BlockSizeBCD.

Example: 'NumGreedyBCD', 150

Data Types: double

'ToleranceBCD' — Relative tolerance on gradient norm

1e-3 (default) | positive scalar

Relative tolerance on gradient norm for terminating block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'ToleranceBCD' and a positive scalar.

Example: 'ToleranceBCD',0.002

Data Types: double

'StepToleranceBCD' — Absolute tolerance on step size

1e-3 (default) | positive scalar

Absolute tolerance on step size for terminating block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'StepToleranceBCD' and a positive scalar.

Example: 'StepToleranceBCD',0.002

Data Types: double

'IterationLimitBCD' — Maximum number of BCD iterations

1000000 (default) | integer value

Maximum number of block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'IterationLimitBCD' and an integer value.

Example: 'IterationLimitBCD',10000

Data Types: double

Optimization

'Optimizer' — Optimizer to use for parameter estimation

'quasnewton' (default) | 'fminsearch' | 'fminunc' | 'fmincon'

Optimizer to use for parameter estimation, specified as the comma-separated pair consisting of 'Optimizer' and one of quasnewton, fminsearch, fminunc, fmincon.

Use of 'fminunc' and 'fmincon' requires an Optimization Toolbox license.

Example: 'Optimizer','fmincon'

'OptimizerOptions' — Options for the optimizer

structure | object

Options for the optimizer you choose using the `Optimizer` name-value pair argument, specified as the comma-separated pair consisting of `'Optimizer'` and a structure or object created by `optimset`, `statset('fitrgp')`, or `optimoptions`.

Optimizer	Create Optimizer Options Using
'fminsearch'	optimset (structure)
'quasnewton'	statset('fitrgp') (structure)
'fminunc' or 'fmincon'	optimoptions (object)

The default options depend on the type of optimizer.

Example: `'OptimizerOptions',opt`

Cross-Validation**'CrossVal' — Indicator for cross-validation**

'off' (default) | 'on'

Indicator for cross-validation, specified as the comma-separated pair consisting of `'CrossVal'` and either `'off'` or `'on'`. If it is `'on'`, then `fitrgp` returns a GPR model cross-validated with 10 folds.

You can use one of the `KFold`, `Holdout`, `Leaveout` or `CVPartition` name-value pair arguments to change the default cross-validation settings. You can use only one of these name-value pairs at a time.

As an alternative, you can use the `crossval` method for your model.

Example: `'CrossVal','on'`

Data Types: double

'CVPartition' — Random partition for a stratified *k*-fold cross-validation

cvpartition object

Random partition for a stratified *k*-fold cross-validation, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` object.

Example: `'CVPartition',cvp` uses the random partition defined by `cvp`.

If you specify `CVPartition`, then you cannot specify `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data to use for testing

Scalar value in the range from 0 to 1

Fraction of the data to use for testing in holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range from 0 to 1. If you specify 'Holdout', p , then the software:

1. Randomly reserves around $p*100\%$ of the data as validation data, and trains the model using the rest of the data
2. Stores the compact, trained model in `cvgprMdl.Trained`.

Example: 'Holdout', 0.3 uses 30% of the data for testing and 70% of the data for training.

If you specify `Holdout`, then you cannot specify `CVPartition`, `KFold`, or `Leaveout`.

Data Types: double

'KFold' — Number of folds

10 (default) | positive integer value

Number of folds to use in cross-validated GPR model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value. `KFold` must be greater than 1. If you specify 'KFold', k then the software:

1. Randomly partitions the data into k sets.
2. For each set, reserves the set as test data, and trains the model using the other $k - 1$ sets.
3. Stores the k compact, trained models in the cells of a k -by-1 cell array in `cvgprMdl.Trained`.

Example: 'KFold', 5 uses 5 folds in cross-validation. That is, for each fold, uses that fold as test data, and trains the model on the remaining 4 folds.

If you specify `KFold`, then you cannot specify `CVPartition`, `Holdout`, or `Leaveout`.

Data Types: double

'Leaveout' — Indicator for leave-one-out cross-validation

'off' (default) | 'on'

Indicator for leave-one-out cross-validation, specified as the comma-separated pair consisting of 'Leaveout' and either 'off' or 'on'.

If you specify `'Leaveout'`, `'on'`, then, for each of the n observations, the software:

1. Reserves the observation as test data, and trains the model using the other $n - 1$ observations.
2. Stores the compact, trained model in a cell in the n -by-1 cell array `cvgprMdl.Trained`.

Example: `'Leaveout'`, `'on'`

If you specify `Leaveout`, then you cannot specify `CVPartition`, `Holdout`, or `KFold`.

Hyperparameter Optimization

'OptimizeHyperparameters' — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'Sigma'}`
- `'all'` — Optimize all eligible parameters, equivalent to `{'BasisFunction', 'KernelFunction', 'KernelScale', 'Sigma', 'Standardize'}`
- Cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitrgp` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 29-3219. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note: `OptimizeHyperparameters` values override any values you set using other name-value pairs. For example, setting `OptimizeHyperparameters` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitrgp` are:

- `BasisFunction` — `fitrgp` searches among `'constant'`, `'none'`, `'linear'`, and `'pureQuadratic'`.

- **KernelFunction** — `fitrgp` searches among `'ardexponential'`, `'ardmatern32'`, `'ardmatern52'`, `'ardrationalquadratic'`, `'ardsquaredexponential'`, `'exponential'`, `'matern32'`, `'matern52'`, `'rationalquadratic'`, and `'squaredexponential'`.
- **KernelScale** — `fitrgp` uses the `KernelParameters` argument to specify the value of the kernel scale parameter, which is held constant during fitting. In this case, all input dimensions are constrained to have the same `KernelScale` value. `fitrgp` searches among real value in the range `[1e-3*MaxPredictorRange,MaxPredictorRange]`, where `MaxPredictorRange = max(max(X) - min(X))`.

`KernelScale` cannot be optimized for any of the ARD kernels.

- **Sigma** — `fitrgp` searches among real value in the range `[1e-4, max(1e-3,10*ResponseStd)]`, where `ResponseStd = std(y)`.

Internally, `fitrgp` sets the `ConstantSigma` name-value pair to `true` so the value of `Sigma` is constant during the fitting.

- **Standardize** — `fitrgp` searches among `true` and `false`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitrgp',meas,species);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression, and the misclassification rate for classification. To control the iterative display, set the `HyperparameterOptimizationOptions` name-value pair, `Verbose` field. To control the plots, set the `HyperparameterOptimizationOptions` name-value pair, `ShowPlots` field.

For an example, see “Optimize GPR Regression” on page 29-2305.

Example: `'auto'`

Data Types: `char` | `cell`

'HyperparameterOptimizationOptions' — Options for optimization

structure

Options for optimization, specified as a structure. Modifies the effect of the `OptimizeHyperparameters` name-value pair. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the <code>commandsortrows</code> (<code>Mdl.ParameterOptim.</code></p>	'bayesopt'
AcquisitionFunc	<ul style="list-style-type: none"> 'expected-improvement-per-second-plus' 'expected-improvement' 'expected-improvement-plus' 'expected-improvement-per-second' 'lower-confidence-bound' 'probability-of-improvement' <p>For details, see the <code>bayesopt</code> <code>AcquisitionFunctionName</code> name-value pair, or “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'

Field Name	Values	Default
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
NumGridDivisions	For 'gridsearch', the number of values in each dimension. Can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. Ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , plots the best objective function value against iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is 'bayesopt', then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediateResults	Logical value indicating whether to save results when <code>Optimizer</code> is 'bayesopt'. If <code>true</code> , overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesoptVerbose</code> name-value pair.	1

Field Name	Values	Default
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code>	<code>Kfold = 5</code>
Holdout	A scalar in the range $(0, 1)$ representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example: `struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Other

'PredictorNames' — Predictor variable names

cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply `X` and `y`, then you can use 'PredictorNames' to give the predictor variables in `X` names.
 - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
 - By default, `PredictorNames` is `{x1,x2,...}`.

- If you supply `tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitrgp` uses the predictor variables in `PredictorNames` and the response only in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It good practice to specify the predictors for training using one of `'PredictorNames'` or `formula` only.

Example: `'PredictorNames', {'PedalLength', 'PedalWidth'}`

Data Types: `cell`

'ResponseName' — Name of the response variable

`'Y'` (default) | character vector

Name of the response variable, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector.

This name-value pair argument is not valid when using the `formula` or `ResponseVarName` input arguments.

Example: `'ResponseName', 'Price'`

Data Types: `char`

'Verbose' — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and one of the following.

- `0` — `fitrgp` suppresses diagnostic messages related to active set selection and block coordinate descent but displays the messages related to parameter estimation, depending on the value of `'Display'` in `OptimizerOptions`.
- `1` — `fitrgp` displays the iterative diagnostic messages related to parameter estimation, active set selection, and block coordinate descent.

Example: `'Verbose', 1`

'CacheSize' — Cache size in megabytes

`1000 MB` (default) | positive scalar

Cache size in megabytes (MB), specified as the comma-separated pair consisting of 'CacheSize' and a positive scalar. Cache size is the extra memory that is available in addition to that required for fitting and active set selection. `fitrgp` uses `CacheSize` to:

- Decide whether interpoint distances should be cached when estimating parameters.
- Decide how matrix vector products should be computed for block coordinate descent method and for making predictions.

Example: 'CacheSize',2000

Data Types: double

Output Arguments

gprMdl — Gaussian process regression model

RegressionGP object | RegressionPartitionedModel object

Gaussian process regression model, returned as a RegressionGP or a RegressionPartitionedModel object.

- If you cross-validate, that is, if you use one of the 'Crossval', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pairs, then `gprMdl` is a `RegressionPartitionedModel` object. You cannot use a `RegressionPartitionedModel` object to make predictions using `predict`. For more information on the methods and properties of this object, see `RegressionPartitionedModel`.
- If you do not cross-validate, then `gprMdl` is a `RegressionGP` object. You can use this object for predictions using the `predict` method. For more information on the methods and properties of this object, see `RegressionGP`.

Definitions

Active Set Selection and Parameter Estimation

For subset of data, subset of regressors, or fully independent conditional approximation fitting methods (FitMethod equal to 'sd', 'sr', or 'fic'), if you do not provide the active set, `fitrgp` selects the active set and computes the parameter estimates in a series of iterations.

In the first iteration, the software uses the initial parameter values in vector $\eta_0 = [\beta_0, \sigma_0, \theta_0]$ to select an active set A_1 . It maximizes the GPR marginal log likelihood or its approximation using η_0 as the initial values and A_1 to compute the new parameter estimates η_1 . Next, it computes the new log likelihood L_1 using η_1 and A_1 .

In the second iteration, the software selects the active set A_2 using the parameter values in η_1 . Then, using η_1 as the initial values and A_2 , it maximizes the GPR marginal log likelihood or its approximation and estimates the new parameter values η_2 . Then using η_2 and A_2 , computes the new log likelihood value L_2 .

The following table summarizes the iterations and what is computed at each iteration.

Iteration Number	Active Set	Parameter Vector	Log Likelihood
1	A_1	η_1	L_1
2	A_2	η_2	L_2
3	A_3	η_3	L_3
...

The software iterates similarly for a specified number of repetitions. You can specify the number of replications for active set selection using the NumActiveSetRepeats name-value pair argument.

Tips

- `fitrgp` accepts any combination of fitting, prediction, and active set selection methods. In some cases it might not be possible to compute the standard deviations of the predicted responses, hence the prediction intervals. See `predict`. And in some cases, using the exact method might be expensive due to the size of the training data.
- The `PredictorNames` property stores one element for each of the original predictor variable names. For example, if there are three predictors, one of which is a categorical variable with three levels, `PredictorNames` is a 1-by-3 cell array of character vectors.
- The `ExpandedPredictorNames` property stores one element for each of the predictor variables, including the dummy variables. For example, if there are three predictors, one of which is a categorical variable with three levels, then `ExpandedPredictorNames` is a 1-by-5 cell array of character vectors.

- Similarly, the **Beta** property stores one beta coefficient for each predictor, including the dummy variables.
- The **X** property stores the training data as originally input. It does not include the dummy variables.

fitrlinear

Fit linear regression model to high-dimensional data

`fitrlinear` efficiently trains linear regression models with high-dimensional, full or sparse predictor data. Available linear regression models include regularized support vector machines (SVM) and least-squares regression methods. `fitrlinear` minimizes the objective function using techniques that reduce computing time (e.g., stochastic gradient descent).

A high-dimensional data set includes many predictor variables. Although such a data set can consume a significant fraction of memory, it must fit in the MATLAB Workspace. For low- through medium-dimensional predictor data sets, see “Alternatives for Lower-Dimensional Data” on page 19-2.

Syntax

```
Mdl = fitrlinear(X,Y)
Mdl = fitrlinear(X,Y,Name,Value)
[Mdl,FitInfo] = fitrlinear(____)
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(____)
```

Description

`Mdl = fitrlinear(X,Y)` returns a trained regression model object that contains the results of fitting a support vector machine regression model to the predictors `X` and response `Y`.

`Mdl = fitrlinear(X,Y,Name,Value)` returns a trained linear regression model with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify implement least-squares regression, specify to cross-validate, or specify the type of regularization. It is good practice to cross-validate using the `Kfold Name,Value` pair argument. The cross-validation results determine how well the model generalizes.

`[Mdl,FitInfo] = fitrlinear(____)` also returns optimization details using any of the previous syntaxes. You cannot request `FitInfo` for cross-validated models.

[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(____) also returns hyperparameter optimization details when you pass an OptimizeHyperparameters name-value pair.

Examples

Train Linear Regression Model

Train a linear regression model using SVM, dual SGD, and ridge regularization.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model. By default, `fitrlinear` uses support vector machines with a ridge penalty, and optimizes using dual SGD for SVM. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

```
[Mdl,FitInfo] = fitrlinear(X,Y)
```

```
Mdl =
```

```
RegressionLinear
  ResponseName: 'Y'
  ResponseTransform: 'none'
           Beta: [1000×1 double]
           Bias: -0.0056
           Lambda: 1.0000e-04
           Learner: 'svm'
```

```

FitInfo =
    struct with fields:
        Lambda: 1.0000e-04
        Objective: 0.2726
        PassLimit: 10
        NumPasses: 10
        BatchLimit: []
        NumIterations: 100000
        GradientNorm: NaN
        GradientTolerance: 0
        RelativeChangeInBeta: 0.4908
        BetaTolerance: 1.0000e-04
        DeltaGradient: 1.5818
        DeltaGradientTolerance: 0.1000
        TerminationCode: 0
        TerminationStatus: {'Maximal number of iterations has been reached.'}
        Alpha: [10000×1 double]
        History: []
        FitTime: 0.0943
        Solver: {'dual'}

```

`Mdl` is a `RegressionLinear` model. You can pass `Mdl` and the training or new data to `loss` to inspect the in-sample mean-squared error. Or, you can pass `Mdl` and new predictor data to `predict` to predict responses for new observations.

`FitInfo` is a structure array containing, among other things, the termination status (`TerminationStatus`) and how long the solver took to fit the model to the data (`FitTime`). It is good practice to use `FitInfo` to determine whether optimization-termination measurements are satisfactory. In this case, `fitrlinear` reached the maximum number of iterations. Because training time is fast, you can retrain the model, but increase the number of passes through the data. Or, try another solver, such as LBFGS.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1} .

```
Lambda = logspace(-5, -1, 15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using SpARSA.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
```

```
numCLModels = numel(CVMdl.Trained)
```

```
numCLModels =
```

```
5
```

CVMdl is a `RegressionPartitionedLinear` model. Because `fitrlinear` implements 5-fold cross-validation, CVMdl contains 5 `RegressionLinear` models that the software trains on each fold.

Display the first trained linear regression model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
```

```
RegressionLinear
  ResponseName: 'Y'
  ResponseTransform: 'none'
  Beta: [1000×15 double]
  Bias: [1×15 double]
  Lambda: [1×15 double]
  Learner: 'leastsquares'
```

Mdl1 is a `RegressionLinear` model object. `fitrlinear` constructed Mdl1 by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of Mdl1 as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated MSE.

```
mse = kfoldLoss(CVMdl);
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
  'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
  log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, `Lambda(10)`).

```
idxFinal = 10;
```

Extract the model with corresponding to the minimal MSE.

```
MdlFinal = selectModels(Mdl,idxFinal)
idxNZCoeff = find(MdlFinal.Beta~=0)
EstCoeff = Mdl.Beta(idxNZCoeff)
```

```
MdlFinal =
```

```
RegressionLinear
```

```

`MdlFinal` is a `RegressionLinear` model with one regularization strength. The nonzero coefficients `EstCoeff` are close to the coefficients that simulated the data.

Optimize a Linear Regression

This example shows how to optimize hyperparameters automatically using `fitrlinear`. The example uses artificial (simulated) data for the model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```

rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);

```

Find hyperparameters that minimize five-fold cross validation loss by using automatic hyperparameter optimization.

For reproducibility, use the 'expected-improvement-plus' acquisition function.

```
hyperopts = struct('AcquisitionFunctionName','expected-improvement-plus');
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(X,Y,...
    'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',hyperopts)
```

Iter	Eval result	Objective	Objective runtime	BestSoFar (observed)	BestSoFar (estim.)	Lambda

This optimization technique is simpler than that shown in “Find Good Lasso Penalty Using Cross-Validation”, but does not allow you to trade off model complexity and cross-validation loss.

Input Arguments

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix.

The length of Y and the number of observations in X must be equal.

Note: If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Y — Response data

numeric vector

Response data, specified as an n -dimensional numeric vector. The length of Y and the number of observations in X must be equal.

Data Types: single | double

Note fitrlinear removes missing observations, that is, observations with any of these characteristics:

- NaN elements in the response (Y or ValidationData{2})
- At least one NaN value in a predictor observation (row in X or ValidationData{1})
- NaN value or 0 weight (Weights or ValidationData{3})

For memory-usage economy, it is best practice to remove observations containing missing values from your training data manually before training.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note: You cannot use any cross-validation name-value pair along with `OptimizeHyperparameters`. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair.

Example:

```
'Learner', 'regression', 'CrossVal', 'on', 'Regularization', 'lasso'
```

specifies to implement least-squares regression, implement 10-fold cross-validation, and specifies to include a lasso regularization term.

Linear Regression Options

'Epsilon' — Half the width of epsilon-insensitive band

`iqr(Y) / 1.349` (default) | nonnegative scalar value

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of 'Epsilon' and a nonnegative scalar value. 'Epsilon' applies to SVM learners only.

The default Epsilon value is `iqr(Y) / 1.349`, which is an estimate of standard deviation using the interquartile range of the response variable `Y`. If `iqr(Y)` is equal to zero, then the default Epsilon value is 0.1.

Example: 'Epsilon', 0.3

Data Types: single | double

'Lambda' — Regularization term strength

'auto' (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto', a nonnegative scalar, or a vector of nonnegative values.

- For 'auto', $\text{Lambda} = 1/n$.

- If you specify a cross-validation, name-value pair argument (e.g., `CrossVal`), then n is the number of in-fold observations.
- Otherwise, n is the training sample size.
- For a vector of nonnegative values, the software sequentially optimizes the objective function for each distinct value in `Lambda` in ascending order.
 - If `Solver` is `'sgd'` or `'asgd'` and `Regularization` is `'lasso'`, then the software does not use the previous coefficient estimates as a warm start for the next optimization iteration. Otherwise, the software uses warm starts.
 - If `Regularization` is `'lasso'`, then any coefficient estimate of 0 retains its value when the software optimizes using subsequent values in `Lambda`.

Returns coefficient estimates for all optimization iterations.

Example: `'Lambda', 10.^(-(10:-2:2))`

Data Types: `char` | `double` | `single`

'Learner' — Linear regression model type

`'svm'` (default) | `'leastsquares'`

Linear regression model type, specified as the comma-separated pair consisting of `'Learner'` and `'svm'` or `'leastsquares'`.

In this table, $f(x) = \beta'x + b$.

- β is a vector of p coefficients.
- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Response range	Loss function
<code>'leastsquares'</code>	Linear regression via ordinary least squares	$y \in (-\infty, \infty)$	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$
<code>'svm'</code>	Support vector machine regression	Same as <code>'leastsquares'</code>	Epsilon-insensitive: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$

Example: 'Learner', 'leastquares'

Data Types: char

'ObservationsIn' — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

Note: If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Data Types: char

'Regularization' — Complexity penalty type

'lasso' | 'ridge'

Complexity penalty type, specified as the comma-separated pair consisting of 'Regularization' and 'lasso' or 'ridge'.

The software composes the objective function for minimization from the sum of the average loss function (see Learner) and the regularization term in this table.

Value	Description
'lasso'	Lasso (L1) penalty: $\lambda \sum_{j=1}^p \beta_j $
'ridge'	Ridge (L2) penalty: $\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$

To specify the regularization term strength, which is λ in the expressions, use Lambda.

The software excludes the bias term (β_0) from the regularization penalty.

If Solver is 'sparsa', then the default value of Regularization is 'lasso'. Otherwise, the default is 'ridge'.

Tip:

- For predictor variable selection, specify `'lasso'`.
- For optimization accuracy, specify `'ridge'`.

Example: `'Regularization','lasso'`

Data Types: char

'Solver' – Objective function minimization technique

`'sgd' | 'asgd' | 'dual' | 'bfgs' | 'lbfgs' | 'sparsa'` | cell vector of character vectors

Objective function minimization technique, specified as the comma-separated pair consisting of `'Solver'` and a value or cell vector of values in this table.

Value	Description	Restrictions
<code>'sgd'</code>	Stochastic gradient descent (SGD) [5][3]	
<code>'asgd'</code>	Average stochastic gradient descent (ASGD) [8]	
<code>'dual'</code>	Dual SGD for SVM [2][7]	Regularization must be <code>'ridge'</code> and Learner must be <code>'svm'</code> .
<code>'bfgs'</code>	Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [4]	Inefficient if X is very high-dimensional.
<code>'lbfgs'</code>	Limited-memory BFGS (LBFGS) [4]	Regularization must be <code>'ridge'</code> .
<code>'sparsa'</code>	Sparse Reconstruction by Separable Approximation (SpaRSA) [6]	Regularization must be <code>'lasso'</code> .

If you specify:

- A ridge penalty (see **Regularization**) and `size(X,1) <= 100` (100 or fewer predictor variables), then the default solver is `'bfgs'`.

- An SVM regression model (see `Learner`), a ridge penalty, and `size(X,1) > 100` (more than 100 predictor variables), then the default solver is `'dual'`.
- A lasso penalty and `X` contains 100 or fewer predictor variables, then the default solver is `'sparsa'`.

Otherwise, the default solver is `'sgd'`.

If you specify a cell vector of solver names, then the software uses all solvers in the specified order for each `Lambda`.

For more details on which solver to choose, see “Tips” on page 29-2377.

Example: `'Solver', {'sgd', 'lbfgs'}`

Data Types: `char` | `cell`

'Beta' — Initial linear coefficient estimates

`zeros(p,1)` (default) | numeric vector | numeric matrix

Initial linear coefficient estimates (β), specified as the comma-separated pair consisting of `'Beta'` and a p -dimensional numeric vector or a p -by- L numeric matrix. p is the number of predictor variables in `X` and L is the number of regularization-strength values (for more details, see `Lambda`).

- If you specify a p -dimensional vector, then the software optimizes the objective function L times using this process.
 - 1 The software optimizes using `Beta` as the initial value and the minimum value of `Lambda` as the regularization strength.
 - 2 The software optimizes again using the resulting estimate from the previous optimization as a warm start, and the next smallest value in `Lambda` as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in `Lambda`.
- If you specify a p -by- L matrix, then the software optimizes the objective function L times. At iteration j , the software uses `Beta(:,j)` as the initial value and, after it sorts `Lambda` in ascending order, uses `Lambda(j)` as the regularization strength.

If you set `'Solver', 'dual'`, then the software ignores `Beta`.

Data Types: `single` | `double`

'Bias' — Initial intercept estimate

numeric scalar | numeric vector

Initial intercept estimate (b), specified as the comma-separated pair consisting of 'Bias' and a numeric scalar or an L -dimensional numeric vector. L is the number of regularization-strength values (for more details, see Lambda).

- If you specify a scalar, then the software optimizes the objective function L times using this process.
 - 1 The software optimizes using **Bias** as the initial value and the minimum value of **Lambda** as the regularization strength.
 - 2 The uses the resulting estimate as a warm start to the next optimization iteration, and uses the next smallest value in **Lambda** as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in **Lambda**.
- If you specify an L -dimensional vector, then the software optimizes the objective function L times. At iteration j , the software uses **Bias**(j) as the initial value and, after it sorts **Lambda** in ascending order, uses **Lambda**(j) as the regularization strength.
- By default:
 - If **Learner** is 'leastquares', then **Bias** is the weighted average of **Y** for training or, for cross-validation, in-fold responses.
 - If **Learner** is 'svm', then **Bias** is the weighted median of **Y** for all training or, for cross-validation, in-fold observations that are greater than **Epsilon**.

Data Types: single | double

'FitBias' — Linear model intercept inclusion flag

true (default) | false

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of 'FitBias' and true or false.

Value	Description
true	The software includes the bias term b in the linear model, and then estimates it.
false	The software sets $b = 0$ during estimation.

Example: 'FitBias', false

Data Types: logical

'PostFitBias' — Flag to fit linear model intercept after optimization

false (default) | true

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of 'PostFitBias' and true or false.

Value	Description
false	The software estimates the bias term b and the coefficients β during optimization.
true	To estimate b , the software: <ol style="list-style-type: none"> 1 Estimates β and b using the model. 2 Computes residuals. 3 Refits b. For least squares, b is the weighted average of the residuals. For SVM regression, b is the weighted median between all residuals with magnitude greater than Epsilon.

If you specify true, then FitBias must be true.

Example: 'PostFitBias', true

Data Types: logical

'Verbose' — Verbosity level

0 (default) | nonnegative integer

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and a nonnegative integer. Verbose controls the amount of diagnostic information fitrlinear displays at the command line.

Value	Description
0	fitrlinear does not display diagnostic information.
1	fitrlinear periodically displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. FitInfo.History contains the diagnostic information.

Value	Description
Any other positive integer	<code>fitrlinear</code> displays and stores diagnostic information at each optimization iteration. <code>FitInfo.History</code> contains the diagnostic information.

Example: `'Verbose', 1`

Data Types: `double` | `single`

SGD and ASGD Solver Options

'BatchSize' — Mini-batch size

positive integer

Mini-batch size, specified as the comma-separated pair consisting of `'BatchSize'` and a positive integer. At each iteration, the software estimates the subgradient using `BatchSize` observations from the training data.

- If X is a numeric matrix, then the default value is 10.
- If X is a sparse matrix, then the default value is $\max([10, \text{ceil}(\text{sqrt}(\text{ff}))])$, where $\text{ff} = \text{numel}(X) / \text{nnz}(X)$ (the *fullness factor* of X).

Example: `'BatchSize', 100`

Data Types: `single` | `double`

'LearnRate' — Learning rate

positive scalar

Learning rate, specified as the comma-separated pair consisting of `'LearnRate'` and a positive scalar. `LearnRate` specifies how many steps to take per iteration. At each iteration, the gradient specifies the direction and magnitude of each step.

- If `Regularization` is `'ridge'`, then `LearnRate` specifies the initial learning rate γ_0 . The software determines the learning rate for iteration t , γ_t , using

$$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$

- λ is the value of `Lambda`.

- If `Solver` is `'sgd'`, then $c = 1$.
- If `Solver` is `'asgd'`, then c is:
 - $2/3$ if `Learner` is `'leastquares'`
 - $3/4$ if `Learner` is `'svm'` [8]
- If `Regularization` is `'lasso'`, then, for all iterations, `LearnRate` is constant.

By default, `LearnRate` is $1/\sqrt{1+\max((\sum(X.^2, \text{obsDim})))}$, where `obsDim` is 1 if the observations compose the columns of `X`, and 2 otherwise.

Example: `'LearnRate', 0.01`

Data Types: `single` | `double`

'OptimizeLearnRate' — Flag to decrease learning rate

`true` (default) | `false`

Flag to decrease the learning rate when the software detects divergence (that is, over-stepping the minimum), specified as the comma-separated pair consisting of `'OptimizeLearnRate'` and `true` or `false`.

If `OptimizeLearnRate` is `'true'`, then:

- 1 For the few optimization iterations, the software starts optimization using `LearnRate` as the learning rate.
- 2 If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.
- 3 The software iterates step 2 until the objective function decreases.

Example: `'OptimizeLearnRate', true`

Data Types: `logical`

'TruncationPeriod' — Number of mini-batches between lasso truncation runs

10 (default) | positive integer

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of `'TruncationPeriod'` and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing $k = \text{TruncationPeriod}$ mini-batches, the software truncates the estimated coefficient j using

$$\hat{\beta}_j^* = \begin{cases} \hat{\beta}_j - u_t & \text{if } \hat{\beta}_j > u_t \\ 0 & \text{if } |\hat{\beta}_j| \leq u_t \\ \hat{\beta}_j + u_t & \text{if } \hat{\beta}_j < -u_t \end{cases}$$

- For SGD, $\hat{\beta}_j$ is the estimate of coefficient j after processing k mini-batches. $u_t = k\gamma_t\lambda$. γ_t is the learning rate at iteration t . λ is the value of **Lambda**.
- For ASGD, $\hat{\beta}_j$ is the averaged estimate coefficient j after processing k mini-batches, $u_t = k\lambda$.

If **Regularization** is 'ridge', then the software ignores **TruncationPeriod**.

Example: 'TruncationPeriod',100

Data Types: single | double

Other Regression Options

'Weights' — Observation weights

ones(size(X,2),1)/size(X,2) (default) | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. **fitrlinear** weighs the observations in **X** with the corresponding value in **Weights**. The size of **Weights** must equal the number of observations in **X**.

fitrlinear normalizes **Weights** to sum to 1.

Data Types: double | single

Cross-Validation Options

'CrossVal' — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, or `KFold`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Example: `'Crossval', 'on'`

Data Types: `char`

'CVPartition' — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', p`, then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify, e.g., `'KFold', k`, then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

Example: 'KFold',8

Data Types: single | double

SGD and ASGD Convergence Controls

'BatchLimit' — Maximal number of batches

positive integer

Maximal number of batches to process, specified as the comma-separated pair consisting of 'BatchLimit' and a positive integer. When the software processes `BatchLimit` batches, it terminates optimization.

- By default:
 - The software passes through the data `PassLimit` times.
 - If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is `ceil(1e6/BatchSize)`. `BatchSize` is the value of the 'BatchSize' name-value pair argument.
- If you specify 'BatchLimit' and 'PassLimit', then the software chooses the argument that results in processing the fewest observations.
- If you specify 'BatchLimit' but not 'PassLimit', then the software processes enough batches to complete up to one entire pass through the data.

Example: 'BatchLimit',100

Data Types: single | double

'BetaTolerance' — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = \begin{bmatrix} \beta_t' & b_t \end{bmatrix}$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance', 1e-6`

Data Types: `single` | `double`

'NumCheckConvergence' — Number of batches to process before next convergence check
positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of `'NumCheckConvergence'` and a positive integer.

To specify the batch size, see `BatchSize`.

The software checks for convergence about 10 times per pass through the entire data set by default.

Example: `'NumCheckConvergence', 100`

Data Types: `single` | `double`

'PassLimit' — Maximal number of passes
1 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer.

`fitrlinear` processes all observations when it completes one pass through the data.

When `fitrlinear` passes through the data `PassLimit` times, it terminates optimization.

If you specify `'BatchLimit'` and `PassLimit`, then `fitrlinear` chooses the argument that results in processing the fewest observations. For more details, see “Algorithms” on page 29-2378.

Example: `'PassLimit', 5`

Data Types: `single` | `double`

'ValidationData' — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 29-2378. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- `ValidationData(2)` must contain an array of m responses with length corresponding to the number of observations in `ValidationData{1}`.
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

'GradientTolerance' — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar. `GradientTolerance` applies to these values of `Solver`: 'bfgs', 'lbfgs', and 'sparsa'.

Let ∇_{L_t} be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla_{L_t}\|_{\infty} = \max|\nabla_{L_t}| < \text{GradientTolerance}$, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when `fitrlinear` satisfies either stopping criterion.

If `fitrlinear` converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, `fitrlinear` uses the next solver specified in `Solver`.

Example: `'GradientTolerance',eps`

Data Types: `single` | `double`

'IterationLimit' — Maximal number of optimization iterations

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer. `IterationLimit` applies to these values of `Solver`: `'bfgs'`, `'lbfgs'`, and `'sparsa'`.

Example: `'IterationLimit',1e7`

Data Types: `single` | `double`

Dual SGD Optimization Convergence Controls

'BetaTolerance' — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = \begin{bmatrix} \beta_t' & b_t \end{bmatrix}$, that is, the vector of the coefficients and the bias term at optimization

iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify `DeltaGradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance',1e-6`

Data Types: `single` | `double`

'DeltaGradientTolerance' — Gradient-difference tolerance

0.1 (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions violators, specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar. `DeltaGradientTolerance` applies to the `'dual'` value of `Solver` only.

- If the magnitude of the KKT violators is less than `DeltaGradientTolerance`, then `fitrlinear` terminates optimization.
- If `fitrlinear` converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, `fitrlinear` uses the next solver specified in `Solver`.

Example: `'DeltaGapTolerance', 1e-2`

Data Types: `double` | `single`

'NumCheckConvergence' — Number of passes through entire data set to process before next convergence check

5 (default) | positive integer

Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of `'NumCheckConvergence'` and a positive integer.

Example: `'NumCheckConvergence', 100`

Data Types: `single` | `double`

'PassLimit' — Maximal number of passes

10 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data `PASSLimit` times, it terminates optimization.

Example: 'PassLimit',5

Data Types: single | double

'ValidationData' — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 29-2378. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- `ValidationData(2)` must contain an array of m responses with length corresponding to the number of observations in `ValidationData{1}`.
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

BFGS, LBFGS, and SpARSA Convergence Controls

'BetaTolerance' — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = \begin{bmatrix} \beta_t' & b_t \end{bmatrix}$, that is, the vector of the coefficients and the bias term at optimization

iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify `GradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance', 1e-6`

Data Types: `single` | `double`

'GradientTolerance' — Absolute gradient tolerance

`1e-6` (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of `'GradientTolerance'` and a nonnegative scalar.

Let ∇_{L_t} be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla_{L_t}\|_{\infty} = \max |\nabla_{L_t}| < \text{GradientTolerance}$, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'GradientTolerance', 1e-5`

Data Types: `single` | `double`

'HessianHistorySize' — Size of history buffer for Hessian approximation

`15` (default) | positive integer

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of `'HessianHistorySize'` and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest `HessianHistorySize` iterations.

The software does not support 'HessianHistorySize' for SpaRSA.

Example: 'HessianHistorySize', 10

Data Types: single | double

'IterationLimit' — Maximal number of optimization iterations

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. `IterationLimit` applies to these values of `Solver`: 'bfgs', 'lbfgs', and 'sparsa'.

Example: 'IterationLimit', 500

Data Types: single | double

'ValidationData' — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 29-2378. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- `ValidationData(2)` must contain an array of m responses with length corresponding to the number of observations in `ValidationData{1}`.
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

Hyperparameter Optimization

'OptimizeHyperparameters' — Parameters to optimize

'none' (default) | 'auto' | 'all' | cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as:

- 'none' — Do not optimize
- 'auto' — Use {'Lambda', 'Learner'}
- 'all' — Optimize all eligible parameters
- cell array of eligible parameter names
- vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitrlinear` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note: `OptimizeHyperparameters` values override any values you set using other name-value pairs. For example, setting `OptimizeHyperparameters` to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitrlinear` are:

- `Lambda` — `fitrlinear` searches among positive values, by default log-scaled in the range $[1e-5/\text{NumObservations}, 1e5/\text{NumObservations}]$.
- `Learner` — `fitrlinear` searches among 'svm' and 'leastsquares'.
- `Regularization` — `fitrlinear` searches among 'ridge' and 'lasso'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load carsmall
params = hyperparameters('fitrlinear',[Horsepower,Weight],MPG);
params(1).Range = [1e-3,2e4];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression, and the misclassification rate for classification. To control the iterative display, set the `HyperparameterOptimizationOptions` name-value pair, `Verbose` field. To control the plots, set the `HyperparameterOptimizationOptions` name-value pair, `ShowPlots` field.

For an example, see “Optimize a Linear Regression” on page 29-2345.

Example: 'auto'

Data Types: char | cell

'HyperparameterOptimizationOptions' — Options for optimization structure

Options for optimization, specified as a structure. Modifies the effect of the `OptimizeHyperparameters` name-value pair. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the <code>commandsortrows(Mdl.ParameterOptim</code></p>	'bayesopt'
AcquisitionFunc	<ul style="list-style-type: none"> 'expected-improvement-per-second-plus' 'expected-improvement' 	'expected-improvement-per-second-plus'

Field Name	Values	Default
	<ul style="list-style-type: none"> • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>For details, see the <code>bayesopt</code> AcquisitionFunctionName name-value pair, or “Acquisition Function Types” on page 10-4.</p>	
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
NumGridDivisions	For 'gridsearch', the number of values in each dimension. Can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. Ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , plots the best objective function value against iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is 'bayesopt', then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediateResults	Logical value indicating whether to save results when <code>Optimizer</code> is 'bayesopt'. If <code>true</code> , overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>

Field Name	Values	Default
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesoptVerbose</code> name-value pair.	1
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code>	Kfold = 5
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example: `struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

Md1 — Trained linear regression model

RegressionLinear model object | RegressionPartitionedLinear cross-validated model object

Trained linear regression model, returned as a `RegressionLinear` model object or `RegressionPartitionedLinear` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `RegressionPartitionedLinear` cross-validated model object. Otherwise, `Mdl` is a `RegressionLinear` model object.

To reference properties of `Mdl`, use dot notation. For example, enter `Mdl.Beta` in the Command Window to display the vector or matrix of estimated coefficients.

Note: Unlike other regression models, and for economical memory usage, `RegressionLinear` and `RegressionPartitionedLinear` model objects do not store the training data or optimization details (for example, convergence history).

FitInfo — Optimization details

structure array

Optimization details, returned as a structure array.

Fields specify final values or name-value pair argument specifications, for example, `Objective` is the value of the objective function when optimization terminates. Rows of multidimensional fields correspond to values of `Lambda` and columns correspond to values of `Solver`.

This table describes some notable fields.

Field	Description				
<code>TerminationStatus</code>	<ul style="list-style-type: none"> Reason for optimization termination Corresponds to a value in <code>TerminationCode</code> 				
<code>FitTime</code>	Elapsed, wall-clock time in seconds				
<code>History</code>	<p>A structure array of optimization information for each iteration. The field <code>Solver</code> stores solver types using integer coding.</p> <table border="1"> <thead> <tr> <th>Integer</th> <th>Solver</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>SGD</td> </tr> </tbody> </table>	Integer	Solver	1	SGD
Integer	Solver				
1	SGD				

Field	Description	
	Integer	Solver
	2	ASGD
	3	Dual SGD for SVM
	4	LBFGS
	5	BFGS
	6	SpaRSA

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.History.Objective`.

It is good practice to examine `FitInfo` to assess whether convergence is satisfactory.

HyperparameterOptimizationResults — Description of the cross-validation optimization of hyperparameters

BayesianOptimization object | table of hyperparameters and associated values

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- 'bayesopt' (default) — Object of class `BayesianOptimization`
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Data Types: `table`

Note: If `Learner` is 'leastsquares', then the loss term in the objective function is half of the MSE. `loss` returns the MSE by default. Therefore, if you use `loss` to check the resubstitution, or training, error then there is a discrepancy between the MSE returned by `loss` and optimization results in `FitInfo` or returned to the command line by setting a positive verbosity level using `Verbose`.

Definitions

Warm Start

A *warm start* is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

Tips

- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify `'ObservationsIn'`, `'columns'`. As a result, you can experience a significant reduction in optimization-execution time.
- For better optimization accuracy if `X` is high-dimensional and `Regularization` is `'ridge'`, set any of these combinations for `Solver`:
 - `'sgd'`
 - `'asgd'`
 - `'dual'` if `Learner` is `'svm'`
 - `{'sgd', 'lbfgs'}`
 - `{'asgd', 'lbfgs'}`
 - `{'dual', 'lbfgs'}` if `Learner` is `'svm'`

Other combinations can result in poor optimization accuracy.

- For better optimization accuracy if `X` is moderate- through low-dimensional and `Regularization` is `'ridge'`, set `Solver` to `'bfgs'`.
- If `Regularization` is `'lasso'`, set any of these combinations for `Solver`:
 - `'sgd'`
 - `'asgd'`
 - `'sparsa'`
 - `{'sgd', 'sparsa'}`
 - `{'asgd', 'sparsa'}`
- When choosing between SGD and ASGD, consider that:
 - SGD takes less time per iteration, but requires more iterations to converge.

- ASGD requires fewer iterations to converge, but takes more time per iteration.
- If X has few observations, but many predictor variables, then:
 - Specify `'PostFitBias', true`.
 - For SGD or ASGD solvers, set `PassLimit` to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.
- For SGD and ASGD solvers, `BatchSize` affects the rate of convergence.
 - If `BatchSize` is too small, then `fitrlinear` achieves the minimum in many iterations, but computes the gradient per iteration quickly.
 - If `BatchSize` is too large, then `fitrlinear` achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.
- Large learning rates (see `LearnRate`) speed up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.
- When using lasso penalties, experiment with various values of `TruncationPeriod`. For example, set `TruncationPeriod` to 1, 10, and then 100.
- For efficiency, `fitrlinear` does not standardize predictor data. To standardize X , enter

```
X = bsxfun(@rdivide, bsxfun(@minus, X, mean(X, 2)), std(X, 0, 2));
```

The code requires that you orient the predictors and observations as the rows and columns of X , respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.

Algorithms

- If you specify `ValidationData`, then, during objective-function optimization:
 - `fitrlinear` estimates the validation loss of `ValidationData` periodically using the current model, and tracks the minimal estimate.
 - When `fitrlinear` estimates a validation loss, it compares the estimate to the minimal estimate.
 - When subsequent, validation loss estimates exceed the minimal estimate five times, `fitrlinear` terminates optimization.

- If you specify `ValidationData` and to implement a cross-validation routine (`CrossVal`, `CVPartition`, `Holdout`, or `KFold`), then:
 - 1 `fitrlinear` randomly partitions `X` and `Y` according to the cross-validation routine that you choose.
 - 2 `fitrlinear` trains the model using the training-data partition. During objective-function optimization, `fitrlinear` uses `ValidationData` as another possible way to terminate optimization (for details, see the previous bullet).
 - 3 Once `fitrlinear` satisfies a stopping criterion, it constructs a trained model based on the optimized linear coefficients and intercept.
 - a If you implement k -fold cross-validation, and `fitrlinear` has not exhausted all training-set folds, then `fitrlinear` returns to Step 2 to train using the next training-set fold.
 - b Otherwise, `fitrlinear` terminates training, and then returns the cross-validated model.
 - 4 You can determine the quality of the cross-validated model. For example:
 - To determine the validation loss using the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldLoss`.
 - To predict observations on the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldPredict`.

Introduced in R2016a

fitrm

Fit repeated measures model

Syntax

```
rm = fitrm(t,modelspec)
rm = fitrm(t,modelspec,Name,Value)
```

Description

`rm = fitrm(t,modelspec)` returns a repeated measures model, specified by `modelspec`, fitted to the variables in the table or dataset array `t`.

`rm = fitrm(t,modelspec,Name,Value)` returns a repeated measures model, with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the hypothesis for the within-subject factors.

Examples

Fit a Repeated Measures Model

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
```

```
Meas = table([1 2 3 4]', 'VariableNames', {'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas)
```

```
rm =
```

```
RepeatedMeasuresModel with properties:
```

```
Between Subjects:
```

```
    BetweenDesign: [150×5 table]
```

```
    ResponseNames: {'meas1' 'meas2' 'meas3' 'meas4'}
```

```
    BetweenFactorNames: {'species'}
```

```
    BetweenModel: '1 + species'
```

```
Within Subjects:
```

```
    WithinDesign: [4×1 table]
```

```
    WithinFactorNames: {'Measurements'}
```

```
    WithinModel: 'separatemeans'
```

```
Estimates:
```

```
    Coefficients: [3×4 table]
```

```
    Covariance: [4×4 table]
```

Display the coefficients.

```
rm.Coefficients
```

```
ans =
```

```
3×4 table
```

	meas1	meas2	meas3	meas4
(Intercept)	5.8433	3.0573	3.758	1.1993
species_setosa	-0.83733	0.37067	-2.296	-0.95333
species_versicolor	0.092667	-0.28733	0.502	0.12667

fitrm uses the 'effects' contrasts which means that the coefficients sum to 0. The `rm.DesignMatrix` has one column of 1s for the intercept, and two other columns `species_setosa` and `species_versicolor`, which are as follows:

$$\text{species_setosa} = \begin{cases} 1 & \text{if setosa} \\ 0 & \text{if versicolor} \\ -1 & \text{if virginica} \end{cases} \quad \text{and} \quad \text{species_versicolor} = \begin{cases} 0 & \text{if setosa} \\ 1 & \text{if versicolor} \\ -1 & \text{if virginica} \end{cases}$$

Display the covariance matrix.

Specify the Within-Subject Hypothesis

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'longitudinalData.mat'));
```

The matrix `Y` contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of `Y` corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to conduct repeated measures analysis.

```
t = table(Gender, Y(:,1), Y(:,2), Y(:,3), Y(:,4), Y(:,5), ...
```

```
'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where blood levels are the responses and gender is the predictor variable. Also define the hypothesis for within-subject factors.

```
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time,'WithinModel','orthogonalcontrasts')
```

```
rm =

The display shows the coefficients for fitting the repeated measures as a function of the terms in the between-subjects model.

Input Arguments

t — Input data

table

Input data, which includes the values of the response variables and the between-subject factors to use as predictors in the repeated measures model, specified as a table.

Data Types: table

modelspec — Formula for model specification

character vector of the form 'y1-yk ~ terms'

Formula for model specification, specified as a character vector of the form 'y1-yk ~ terms'. The responses and terms are specified using Wilkinson notation. `fitrm` treats the variables used in model terms as categorical if they are categorical (nominal or ordinal), logical, char arrays, or a cell arrays of character vectors.

For example, if you have four repeated measures as responses and the factors `x1`, `x2`, and `x3` as the predictor variables, then you can define a repeated measures model as follows.

Example: 'y1-y4 ~ x1 + x2 * x3'

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: 'WithinDesign', 'W', 'WithinModel', 'w1+w2' specifies the matrix `w` as the design matrix for within-subject factors, and the model for within-subject factors `w1` and `w2` is 'w1+w2'.

'WithinDesign' — Design for within-subject factors

numeric vector of length r (default) | r -by- k numeric matrix | r -by- k table

Design for within-subject factors, specified as the comma-separated pair consisting of 'WithinDesign' and one of the following:

- Numeric vector of length r , where r is the number of repeated measures.

In this case, `fitrm` treats the values in the vector as continuous, and these are typically time values.

- r -by- k numeric matrix of the values of the k within-subject factors, w_1, w_2, \dots, w_k .

In this case, `fitrm` treats all k variables as continuous.

- r -by- k table that contains the values of the k within-subject factors.

In this case, `fitrm` treats all numeric variables as continuous, and all categorical variables as categorical.

For example, if the table `weeks` contains the values of the within-subject factors, then you can define the design table as follows.

Example: 'WithinDesign', weeks

Data Types: single | double | table

'WithinModel' — Model specifying within-subject hypothesis test

'separatemeans' (default) | 'orthogonalcontrasts' | character vector that defines a model

Model specifying the within-subject hypothesis test, specified as the comma-separated pair consisting of 'WithinModel' and one of the following:

- 'separatemeans' — Compute a separate mean for each group.
- 'orthogonalcontrasts' — This is valid only when the within-subject model has a single numeric factor T . Responses are the average, the slope of centered T , and, in general, all orthogonal contrasts for a polynomial up to $T^{(p-1)}$, where p is the number of rows in the within-subject model.
- A character vector that defines a model specification in the within-subject factors. You can define the model based on the rules for the `terms` in `modelspec`.

For example, if there are three within-subject factors `w1`, `w2`, and `w3`, then you can specify a model for the within-subject factors as follows.

Example: 'WithinModel', 'w1+w2+w2*w3'

Data Types: char

Output Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

Definitions

Model Specification Using Wilkinson Notation

Wilkinson notation describes the factors present in models. It does not describe the multipliers (coefficients) of those factors.

The following rules specify the responses in `modelspec`.

Wilkinson Notation	Meaning
Y1, Y2, Y3	Specific list of variables
Y1 - Y5	All table variables from Y1 through Y5

The following rules specify terms in `modelspec`.

Wilkinson notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1 * X2$
$X1 : X2$	$X1 * X2$ only
$-X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$

Wilkinson notation	Factors in Standard Notation
$X1 * (X2 + X3)$	X1, X2, X3, X1*X2, X1*X3

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

RepeatedMeasuresModel

Introduced in R2014a

fitdist

Fit probability distribution object to data

Syntax

```
pd = fitdist(x,distname)
pd = fitdist(x,distname,Name,Value)

[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)
[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)
```

Description

`pd = fitdist(x,distname)` creates a probability distribution object by fitting the distribution specified by `distname` to the data in column vector `x`.

`pd = fitdist(x,distname,Name,Value)` creates the probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)` creates probability distribution objects by fitting the distribution specified by `distname` to the data in `x` based on the grouping variable `groupvar`. It returns a cell array of fitted probability distribution objects, `pdca`, a cell array of group labels, `gn`, and a cell array of grouping variable levels, `gl`.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)` returns the above output arguments using additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

Examples

Fit a Normal Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 154 [148.728, 159.272]
sigma = 26.5714 [23.3299, 30.8674]
```

Plot the pdf of the distribution.

```
x_values = 50:1:250;
y = pdf(pd,x_values);
plot(x_values,y, 'LineWidth',2)
```

Fit a Kernel Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create a kernel distribution object by fitting it to the data. Use the Epanechnikov kernel function.

```
pd = fitdist(x,'Kernel','Kernel','epanechnikov')
```

```
pd =
```

```
KernelDistribution
```

```
Kernel = epanechnikov  
Bandwidth = 14.3792  
Support = unbounded
```

Plot the pdf of the distribution.

```
x_values = 50:1:250;  
y = pdf(pd,x_values);  
plot(x_values,y)
```

Fit Normal Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create normal distribution objects by fitting them to the data, grouped by patient gender.

```
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Normal','By',gender)
```

```
pdca =
```

```
1×2 cell array
    [1×1 prob.NormalDistribution]    [1×1 prob.NormalDistribution]

gn =
2×1 cell array
    'Female'
    'Male'

g1 =
2×1 cell array
    'Female'
    'Male'
```

The cell array `pdca` contains two probability distribution objects, one for each gender group. The cell array `gn` contains two group labels. The cell array `g1` contains two group levels.

View each distribution in the cell array `pdca` to compare the mean, `mu`, and the standard deviation, `sigma`, grouped by patient gender.

```
female = pdca{1} % Distribution for females
```

```
female =
NormalDistribution

Normal distribution
    mu = 130.472    [128.183, 132.76]
    sigma = 8.30339    [6.96947, 10.2736]
```

```
male = pdca{2} % Distribution for males
```

```
male =  
  
    NormalDistribution  
  
    Normal distribution  
        mu = 180.532    [177.833, 183.231]  
        sigma = 9.19322    [7.63933, 11.5466]
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;  
femalepdf = pdf(female,x_values);  
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure  
plot(x_values,femalepdf,'LineWidth',2)  
hold on  
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)  
legend(gn,'Location','NorthEast')  
hold off
```

Fit Kernel Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create kernel distribution objects by fitting them to the data, grouped by patient gender. Use a triangular kernel function.

```
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Kernel','By',gender,'Kernel','triangle');
```

View each distribution in the cell array `pdca` to see the kernel distributions for each gender.

```
female = pdca{1} % Distribution for females
```

```
female =
```

```
KernelDistribution
```

```
Kernel = triangle  
Bandwidth = 4.25894  
Support = unbounded
```

```
male = pdca{2} % Distribution for males
```

```
male =
```

```
KernelDistribution
```

```
Kernel = triangle  
Bandwidth = 5.08961  
Support = unbounded
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;  
femalepdf = pdf(female,x_values);  
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure  
plot(x_values,femalepdf,'LineWidth',2)  
hold on  
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)  
legend(gn,'Location','NorthEast')  
hold off
```

Input Arguments

x — Input data

column vector

Input data, specified as a column vector. `fitdist` ignores NaN values in `x`. Additionally, any NaN values in the censoring vector or frequency vector causes `fitdist` to ignore the corresponding values in `x`.

Data Types: `single` | `double`

distname — Distribution name

character vector

Distribution name, specified as one of the following character vectors. The distribution specified by `distname` determines the class type of the returned probability distribution object.

Distribution Name	Description	Distribution Class
'Beta'	Beta distribution	prob.BetaDistribution
'Binomial'	Binomial distribution	prob.BinomialDistribution
'BirnbauSaunders'	Birnbau-Saunders distribution	prob.BirnbauSaundersDistribution
'Burr'	Burr distribution	prob.BurrDistribution
'Exponential'	Exponential distribution	prob.ExponentialDistribution
'ExtremeValue'	Extreme Value distribution	prob.ExtremeValueDistribution
'Gamma'	Gamma distribution	prob.GammaDistribution
'GeneralizedExtremeVal'	Generalized Extreme Value distribution	prob.GeneralizedExtremeValueDistribution
'GeneralizedPareto'	Generalized Pareto distribution	prob.GeneralizedParetoDistribution
'HalfNormal'	Half-normal distribution	prob.HalfNormalDistribution
'InverseGaussian'	Inverse Gaussian distribution	prob.InverseGaussianDistribution
'Kernel'	Kernel distribution	prob.KernelDistribution
'Logistic'	Logistic distribution	prob.LogisticDistribution
'Loglogistic'	Loglogistic distribution	prob.LoglogisticDistribution
'Lognormal'	Lognormal distribution	prob.LognormalDistribution
'Nakagami'	Nakagami distribution	prob.NakagamiDistribution
'NegativeBinomial'	Negative Binomial distribution	prob.NegativeBinomialDistribution
'Normal'	Normal distribution	prob.NormalDistribution
'Poisson'	Poisson distribution	prob.PoissonDistribution
'Rayleigh'	Rayleigh distribution	prob.RayleighDistribution

Distribution Name	Description	Distribution Class
'Rician'	Rician distribution	prob.RicianDistribution
'Stable'	Stable distribution	prob.StableDistribution
'tLocationScale'	t Location-Scale distribution	prob.tLocationScaleDistribution
'Weibull'	Weibull distribution	prob.WeibullDistribution

groupvar — Grouping variable

categorical array | logical or numeric vector | cell array of character vectors

Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of character vectors. Each unique value in a grouping variable defines a group.

For example, if `Gender` is a cell array of character vectors with values 'Male' and 'Female', you can use `Gender` as a grouping variable to fit a distribution to your data by gender.

More than one grouping variable can be used by specifying a cell array of grouping variable names. Observations are placed in the same group if they have common values of all specified grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array `{Gender, Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker.

Example: `{Gender, Smoker}`

Data Types: single | double | logical | cell | char

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `fitdist(x, 'Kernel', 'Kernel', 'triangle')` fits a kernel distribution object to the data in `x` using a triangular kernel function.

'Censoring' — Logical flag for censored data

0 (default) | vector of logical values

Logical flag for censored data, specified as the comma-separated pair consisting of `'Censoring'` and a vector of logical values that is the same size as input vector `x`. The value is 1 when the corresponding element in `x` is a right-censored observation and 0 when the corresponding elements is an exact observation. The default is a vector of 0s, indicating that all observations are exact.

`fitdist` ignores any NaN values in this censoring vector. Additionally, any NaN values in `x` or the frequency vector causes `fitdist` to ignore the corresponding values in the censoring vector.

Data Types: `logical`

'Frequency' — Observation frequency

1 (default) | vector of nonnegative integer values

Observation frequency, specified as the comma-separated pair consisting of `'Frequency'` and a vector of nonnegative integer values that is the same size as input vector `x`. Each element of the frequency vector specifies the frequencies for the corresponding elements in `x`. The default is a vector of 1s, indicating that each value in `x` only appears once.

`fitdist` ignores any NaN values in this frequency vector are ignored by the fitting calculations. Additionally, any NaN values in `x` or the censoring vector causes `fitdist` to ignore the corresponding values in the frequency vector.

Data Types: `logical`

'Options' — Control parameters

structure

Control parameters for the iterative fitting algorithm, specified as the comma-separated pair consisting of `'Options'` and a structure you create using `statset`.

Data Types: `struct`

'NTrials' — Number of trials

positive integer value

Number of trials for the binomial distribution, specified as the comma-separated pair consisting of `'NTrials'` and a positive integer value. You must specify `distname` as `'Binomial'` to use this option.

Data Types: `single` | `double`

'Theta' — Threshold parameter

0 (default) | scalar value

Threshold parameter for the generalized Pareto distribution, specified as the comma-separated pair consisting of `'Theta'` and a scalar value. You must specify `distname` as `'GeneralizedPareto'` to use this option.

Data Types: `single` | `double`

'Kernel' — Kernel smoother type

`'normal'` (default) | `'box'` | `'triangle'` | `'epanechnikov'`

Kernel smoother type, specified as the comma-separated pair consisting of `'Kernel'` and one of the following:

- `'normal'`
- `'box'`
- `'triangle'`
- `'epanechnikov'`

You must specify `distname` as `'Kernel'` to use this option.

'Support' — Kernel density support

`'unbounded'` (default) | `'positive'` | two-element vector

Kernel density support, specified as the comma-separated pair consisting of `'Support'` and `'unbounded'`, `'positive'`, or a two-element vector.

`'unbounded'` Density can extend over the whole real line.

`'positive'` Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

You must specify `distname` as `'Kernel'` to use this option.

Data Types: `single` | `double`

'Width' — Bandwidth of kernel smoothing window

scalar value

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of 'Width' and a scalar value. The default value used by `fitdist` is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes. You must specify `distname` as 'Kernel' to use this option.

Data Types: `single` | `double`

Output Arguments

pd — Probability distribution

probability distribution object

Probability distribution, returned as a probability distribution object. The distribution specified by `distname` determines the class type of the returned probability distribution object.

pdca — Probability distribution objects

cell array

Probability distribution objects of the type specified by `distname`, returned as a cell array.

gn — Group labels

cell array of character vectors

Group labels, returned as a cell array of character vectors.

g1 — Grouping variable levels

cell array of character vectors

Grouping variable levels, returned as a cell array of character vectors containing one column for each grouping variable.

Algorithms

The `fitdist` function fits most distributions using maximum likelihood estimation. Two exceptions are the normal and lognormal distributions with uncensored data.

- For the uncensored normal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance.
- For the uncensored lognormal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance of the log of the data.

Alternative Functionality

App

The Distribution Fitter app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitter app using `distributionFitter`, or click Distribution Fitter on the Apps tab.

`distributionFitter` | `makedist`

Introduced in R2009a

fitensemble

Fit ensemble of learners for classification and regression

`fitensemble` can boost or bag decision tree learners or discriminant analysis classifiers. The function can also train random subspace ensembles of KNN or discriminant analysis classifiers.

For simpler interfaces that fit classification and regression ensembles, instead use `fitcensemble` and `fitrensemble`, respectively. Also, `fitcensemble` and `fitrensemble` provide options for Bayesian optimization.

Syntax

```
Mdl = fitensemble(Tbl,ResponseVarName,Method,NLearn,Learners)
```

```
Mdl = fitensemble(Tbl,formula,Method,NLearn,Learners)
```

```
Mdl = fitensemble(Tbl,Y,Method,NLearn,Learners)
```

```
Mdl = fitensemble(X,Y,Method,NLearn,Learners)
```

```
Mdl = fitensemble( ____,Name,Value)
```

Description

`Mdl = fitensemble(Tbl,ResponseVarName,Method,NLearn,Learners)` returns a trained ensemble model object that contains the results of fitting an ensemble of `NLearn` classification or regression learners (`Learners`) to all variables in the table `Tbl`. `ResponseVarName` is the name of the response variable in `Tbl`. `Method` is the ensemble-aggregation method.

`Mdl = fitensemble(Tbl,formula,Method,NLearn,Learners)` fits the model specified by `formula`.

`Mdl = fitensemble(Tbl,Y,Method,NLearn,Learners)` treats all variables in `Tbl` as predictor variables. `Y` is the response variable that is not in `Tbl`.

`Mdl = fitensemble(X,Y,Method,NLearn,Learners)` trains an ensemble using the predictor data in `X` and response data in `Y`.

`Mdl = fitensemble(___, Name, Value)` trains an ensemble using additional options specified by one or more `Name, Value` pair arguments and any of the previous syntaxes. For example, you can specify the class order, to implement 10-fold cross-validation, or the learning rate.

Examples

Estimate the Resubstitution Loss of a Boosting Ensemble

Estimate the resubstitution loss of a trained, boosting classification ensemble of decision trees.

Load the `ionosphere` data set.

```
load ionosphere;
```

Train a decision tree ensemble using `AdaBoost`, 100 learning cycles, and the entire data set.

```
ClassTreeEns = fitensemble(X,Y, 'AdaBoostM1', 100, 'Tree');
```

`ClassTreeEns` is a trained `ClassificationEnsemble` ensemble classifier.

Determine the cumulative resubstitution losses (i.e., the cumulative misclassification error of the labels in the training data).

```
rsLoss = resubLoss(ClassTreeEns, 'Mode', 'Cumulative');
```

`rsLoss` is a 100-by-1 vector, where element k contains the resubstitution loss after the first k learning cycles.

Plot the cumulative resubstitution loss over the number of learning cycles.

```
plot(rsLoss);  
xlabel('Number of Learning Cycles');  
ylabel('Resubstitution Loss');
```

In general, as the number of decision trees in the trained classification ensemble increases, the resubstitution loss decreases.

A decrease in resubstitution loss might indicate that the software trained the ensemble sensibly. However, you cannot infer the predictive power of the ensemble by this decrease. To measure the predictive power of an ensemble, estimate the generalization error by:

- 1 Randomly partitioning the data into training and cross-validation sets. Do this by specifying `'holdout'`, `holdoutProportion` when you train the ensemble using `fitensemble`.

- 2 Passing the trained ensemble to `kfoldLoss`, which estimates the generalization error.

Train Regression Ensemble

Use a trained, boosted regression tree ensemble to predict the fuel economy of a car. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors. Then, train an ensemble using fewer predictors and compare its in-sample predictive accuracy against the first ensemble.

Load the `carsmall` data set. Store the training data in a table.

```
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

Specify a regression tree template that uses surrogate splits to improve predictive accuracy in the presence of NaN values.

```
t = templateTree('Surrogate','On');
```

Train the regression tree ensemble using LSBoost and 100 learning cycles.

```
Mdl1 = fitensemble(Tbl,'MPG','LSBoost',100,t);
```

`Mdl1` is a trained `RegressionEnsemble` regression ensemble. Because `MPG` is a variable in the MATLAB® Workspace, you can obtain the same result by entering

```
Mdl1 = fitensemble(Tbl,MPG,'LSBoost',100,t);
```

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

```
predMPG = predict(Mdl1,[4 200 150 3000])
```

```
predMPG =
    22.8462
```

The average fuel economy of a car with these specifications is 21.78 mpg.

Train a new ensemble using all predictors in `Tbl` except `Displacement`.

```
formula = 'MPG ~ Cylinders + Horsepower + Weight';
```

```
Mdl2 = fitensemble(Tbl,formula,'LSBoost',100,t);
```

Compare the resubstitution MSEs between Mdl1 and Mdl2.

```
mse1 = resubLoss(Mdl1)
mse2 = resubLoss(Mdl2)
```

```
mse1 =
    6.4721
```

```
mse2 =
    7.8599
```

The in-sample MSE for the ensemble that trains on all predictors is lower.

Estimate the Generalization Error of a Boosting Ensemble

Estimate the generalization error of a trained, boosting classification ensemble of decision trees.

Load the `ionosphere` data set.

```
load ionosphere;
```

Train a decision tree ensemble using `AdaBoostM1`, 100 learning cycles, and half of the data chosen randomly. The software validates the algorithm using the remaining half.

```
rng(2); % For reproducibility
ClassTreeEns = fitensemble(X,Y,'AdaBoostM1',100,'Tree',...
    'Holdout',0.5);
```

`ClassTreeEns` is a trained `ClassificationEnsemble` ensemble classifier.

Determine the cumulative generalization error, i.e., the cumulative misclassification error of the labels in the validation data).

```
genError = kfoldLoss(ClassTreeEns,'Mode','Cumulative');
```

`genError` is a 100-by-1 vector, where element k contains the generalization error after the first k learning cycles.

Plot the generalization error over the number of learning cycles.

```
plot(genError);  
xlabel('Number of Learning Cycles');  
ylabel('Generalization Error');
```

The cumulative generalization error decreases to approximately 7% when 25 weak learners compose the ensemble classifier.

Find the Optimal Number of Splits and Trees for an Ensemble

You can control the depth of the trees in an ensemble of decision trees. You can also control the tree depth in an ECOC model containing decision tree binary learners using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters.

- When bagging decision trees, `fitensemble` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.
- When boosting decision trees, `fitensemble` grows stumps (a tree with one split) by default. You can grow deeper trees for better accuracy.

Load the `carsmall` data set. Specify the variables `Acceleration`, `Displacement`, `Horsepower`, and `Weight` as predictors, and `MPG` as the response.

```
load carsmall
X = [Acceleration Displacement Horsepower Weight];
Y = MPG;
```

The default values of the tree depth controllers for boosting regression trees are:

- 1 for `MaxNumSplits`. This option grows stumps.
- 5 for `MinLeafSize`
- 10 for `MinParentSize`

To search for the optimal number of splits:

- 1 Train a set of ensembles. Exponentially increase the maximum number of splits for subsequent ensembles from stump to at most $n - 1$ splits. Also, decrease the learning rate for each ensemble from 1 to 0.1.
- 2 Cross validate the ensembles.
- 3 Estimate the cross-validated mean-squared error (MSE) for each ensemble.
- 4 Compare the cross-validated MSEs. The ensemble with the lowest one performs the best, and indicates the optimal maximum number of splits, number of trees, and learning rate for the data set.

Grow and cross validate a deep regression tree and a stump. Specify to use surrogate splits because the data contain missing values. These serve as benchmarks.

```
MdlDeep = fitrtree(X,Y,'CrossVal','on','MergeLeaves','off',...
    'MinParentSize',1,'Surrogate','on');
MdlStump = fitrtree(X,Y,'MaxNumSplits',1,'CrossVal','on','Surrogate','on');
```

Train the boosting ensembles using 150 regression trees. Cross validate the ensemble using 5-fold cross validation. Vary the maximum number of splits using the values in the sequence $\{2^0, 2^1, \dots, 2^m\}$, where m is such that 2^m is no greater than $n - 1$. For each variant, adjust the learning rate to each value in the set $\{0.1, 0.25, 0.5, 1\}$;

```
n = size(X,1);
```

```

m = floor(log2(n - 1));
lr = [0.1 0.25 0.5 1];
maxNumSplits = 2.^(0:m);
numTrees = 150;
Mdl = cell(numel(maxNumSplits),numel(lr));
rng(1); % For reproducibility
for k = 1:numel(lr);
    for j = 1:numel(maxNumSplits);
        t = templateTree('MaxNumSplits',maxNumSplits(j),'Surrogate','on');
        Mdl{j,k} = fitensemble(X,Y,'LSBoost',numTrees,t,...
            'Type','regression','KFold',5,'LearnRate',lr(k));
    end;
end;

```

Compute the cross-validated MSE for each ensemble.

```

kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(lr)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);

```

Plot how the cross-validated MSE behaves as the number of trees in the ensemble increases for a few of the ensembles, the deep tree, and the stump. Plot the curves with respect to learning rate in the same plot, and plot separate plots for varying tree complexities. Choose a subset of tree complexity levels.

```

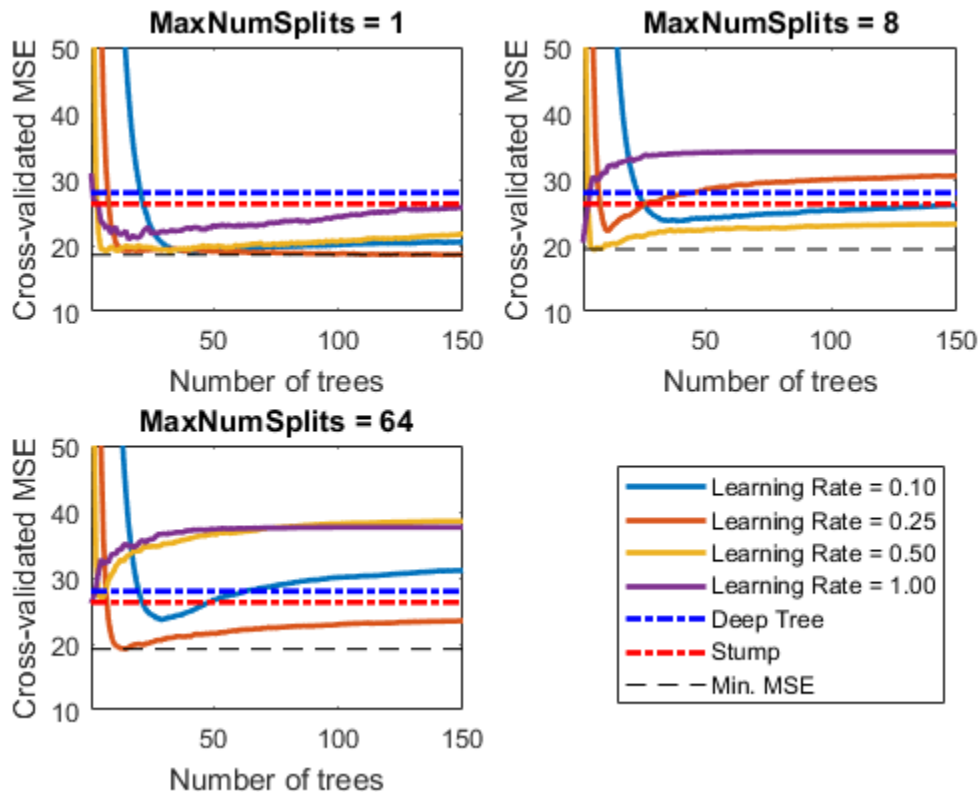

mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3;
    subplot(2,2,k);
    plot(squeeze(error(:,mnsPlot(k),:)), 'LineWidth',2);
    axis tight;
    hold on;
    h = gca;
    plot(h.XLim,[errorDeep errorDeep], '-.b', 'LineWidth',2);
    plot(h.XLim,[errorStump errorStump], '-.r', 'LineWidth',2);
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1], '--k');
    h.YLim = [10 50];
    xlabel 'Number of trees';
    ylabel 'Cross-validated MSE';
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))));
    hold off;
end;
hL = legend([cellstr(num2str(lr),'Learning Rate = %0.2f'));...

```

```

    'Deep Tree'; 'Stump'; 'Min. MSE']);
hL.Position(1) = 0.6;

```

Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.

```

[minErr,minErrIdxLin] = min(error(:));
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);

fprintf('\nMin. MSE = %0.5f',minErr)
fprintf('\nOptimal Parameter Values:\nNum. Trees = %d',idxNumTrees);

```

```
fprintf('\nMaxNumSplits = %d\nLearning Rate = %0.2f\n',...
        maxNumSplits(idxMNS),lr(idxLR))
```

```
Min. MSE = 18.42979
Optimal Parameter Values:
Num. Trees = 1
MaxNumSplits = 4
Learning Rate = 1.00
```

For a different approach to optimizing this ensemble, see “Optimize a Boosted Regression Ensemble”.

- “Supervised Learning Workflow and Algorithms” on page 18-2
- “Ensemble Methods” on page 18-71

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of **Tbl** corresponds to one observation, and each column corresponds to one predictor variable. **Tbl** can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If **Tbl** contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using **ResponseVarName**.
- If **Tbl** contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using **formula**.
- If **Tbl** does not contain the response variable, then specify the response data using **Y**. The length of response variable and the number of rows of **Tbl** must be equal.

Note: To save memory and execution time, supply **X** and **Y** instead of **Tbl**.

Data Types: table

ResponseVarName — Response variable name

name of response variable in **Tbl**

Response variable name, specified as the name of the response variable in `Tbl`.

You must specify `ResponseVarName` as a character vector. For example, if `Tbl.Y` is the response variable, then specify `ResponseVarName` as `'Y'`. Otherwise, `fitensemble` treats all columns of `Tbl` as predictor variables.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

For classification, you can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitensemble` determines the class order, and stores it in the `Mdl.ClassNames`.

Data Types: `char`

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char`

X — Predictor data

numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: double | single

Y — Response data

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Response data, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Each entry in **Y** is the response to or label for the observation in the corresponding row of **X** or **Tbl**. The length of **Y** and the number of rows of **X** or **Tbl** must be equal. If the response variable is a character array, then each element must correspond to one row of the array.

- For classification, **Y** can be any of the supported data types. You can specify the order of the classes using the **ClassNames** name-value pair argument. Otherwise, **fitensemble** determines the class order, and stores it in the **Mdl.ClassNames**.
- For regression, **Y** must be a numeric column vector.

Data Types: char | cell | categorical | logical | single | double

Method — Ensemble-aggregation method

character vector

Ensemble-aggregation method, specified as one of the method names in this list.

- For classification with two classes:
 - 'AdaBoostM1'
 - 'LogitBoost'
 - 'GentleBoost'
 - 'RobustBoost' (requires Optimization Toolbox)
 - 'LPBoost' (requires Optimization Toolbox)
 - 'TotalBoost' (requires Optimization Toolbox)
 - 'RUSBoost'
 - 'Subspace'
 - 'Bag'
- For classification with three or more classes:
 - 'AdaBoostM2'

- 'LPBoost' (requires Optimization Toolbox)
- 'TotalBoost' (requires Optimization Toolbox)
- 'RUSBoost'
- 'Subspace'
- 'Bag'
- For regression:
 - 'LSBoost'
 - 'Bag'

Because you can specify 'Bag' for classification and regression problems, specify the problem type using the `Type` name-value pair argument.

Data Types: `char`

NLearn — Number of ensemble learning cycles

positive integer | 'AllPredictorCombinations'

Number of ensemble learning cycles, specified as a positive integer or 'AllPredictorCombinations'.

- If you specify a positive integer, then, at every learning cycle, the software trains one weak learner for every template object in `Learners`. Consequently, the software trains `NLearn* numel(Learners)` learners.
- If you specify 'AllPredictorCombinations', then set `Method` to 'Subspace' and specify one learner only in `Learners`. With these settings, the software trains learners for all possible combinations of predictors taken `NPredToSample` at a time. Consequently, the software trains `nchoosek(size(X,2),NPredToSample)` learners.

The software composes the ensemble using all trained learners and stores them in `Mdl.Trained`.

For more details, see “Tips” on page 29-2432.

Data Types: `single` | `double` | `char`

Learners — Weak learners to use in ensemble

weak-learner name | weak-learner template object | cell vector of weak-learner template objects

Weak learners to use in the ensemble, specified as a weak-learner name, weak-learner template object, or cell array of weak-learner template objects.

Weak Learner	Weak-Learner Name	Template Object Creation Function	Method Settings
Discriminant analysis	'Discriminant'	templateDiscriminant	Recommended for 'Subspace'
k nearest neighbors	'KNN'	templateKNN	For 'Subspace' only
Decision tree	'Tree'	templateTree	All methods except 'Subspace'

For more details, see `NLearn` and “Tips” on page 29-2432.

Example: For an ensemble composed of two types of classification trees, supply `{t1 t2}`, where `t1` and `t2` are classification tree templates.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'CrossVal', 'on', 'LearningRate', 0.05` specifies to implement 10-fold cross-validation and to use 0.05 as the learning rate.

General Ensemble Options

'CategoricalPredictors' — Categorical predictors list

character matrix | logical vector | numeric vector | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- A numeric vector with indices from 1 through p , where p is the number of columns of X .
- A logical vector of length p , where a `true` entry means that the corresponding column of X is a categorical variable.

- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
- `'all'`, meaning all predictors are categorical.

Specification of `CategoricalPredictors` is appropriate if:

- `'tree'`
- `'knn'`, when all predictors are categorical

By default, if the predictor data is in a matrix (`X`), `fitensemble` assumes that none of the predictors are categorical. If the predictor data is in a table (`Tbl`), `fitensemble` assumes that a variable is categorical if it contains logical values, categorical values, or a cell array of character vectors.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `char`

'NPrint' — Printout frequency

`'off'` (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of `'NPrint'` and a positive integer or `'off'`.

To track the number of *weak learners* or *folds* that `fitensemble` trained so far, specify a positive integer. That is, if you specify the positive integer m :

- Without also specifying any cross-validation option (for example, `CrossVal`), then `fitensemble` displays a message to the command line every time it completes training m weak learners.
- And a cross-validation option, then `fitensemble` displays a message to the command line every time it finishes training m folds.

If you specify `'off'`, then `fitensemble` does not display a message when it completes training weak learners.

Tip: When training an ensemble of many weak learners on a large data set, specify a positive integer for `NPrint`.

Example: 'NPrint',5

Data Types: single | double | char

'PredictorNames' — Predictor variable names

cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
 - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
 - By default, PredictorNames is {x1,x2,...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitensemble uses the predictor variables in PredictorNames and the response only in training.
 - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
 - By default, PredictorNames contains the names of all predictor variables.
 - It good practice to specify the predictors for training using one of 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: cell

'ResponseName' — Response variable name

'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.

- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName', 'response'`

Data Types: `char`

'Type' — Supervised learning type

`'classification' | 'regression'`

Supervised learning type, specified as the comma-separated pair consisting of `'Type'` and `'classification'` or `'regression'`.

- If `Method` is `'bag'`, then the supervised learning type is ambiguous. Therefore, specify `Type` when bagging.
- Otherwise, the value of `Method` determines the supervised learning type.

Example: `'Type', 'classification'`

Data Types: `char`

Cross-Validation Options

'CrossVal' — Cross-validation flag

`'off' (default) | 'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval` or `crossval`.

Example: `'Crossval', 'on'`

Data Types: `char`

'CVPartition' — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Holdout',0.1

Data Types: double | single

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'KFold',5

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations, where n is `size(Mdl.X,1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Leaveout', 'on'

Data Types: char

Other Classification or Regression Options

'ClassNames' — Names of classes to use for training

categorical array | cell array of character vectors | character array | logical vector | numeric vector

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` must be the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.

- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is $\{ 'a', 'b', 'c' \}$. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames', $\{ 'a', 'c' \}$.

The default is the set of all distinct class names in Y .

Example: 'ClassNames', $\{ 'b', 'g' \}$

Data Types: categorical | char | logical | single | double | cell

'Cost' — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure. If you specify:

- The square matrix **Cost**, then $\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i . That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of **Cost**, also specify the **ClassNames** name-value pair argument.
- The structure **S**, then it must have two fields:
 - **S.ClassNames**, which contains the class names as a variable of the same data type as Y
 - **S.ClassificationCosts**, which contains the cost matrix with rows and columns ordered as in **S.ClassNames**

The default is $\text{ones}(K) - \text{eye}(K)$, where K is the number of distinct classes.

Note: `fitensemble` uses **Cost** to adjust the prior class probabilities specified in **Prior**. Then, `fitensemble` uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: 'Cost', $[0 \ 1 \ 2 \ ; \ 1 \ 0 \ 2; \ 2 \ 2 \ 0]$

Data Types: double | single | struct

'Prior' — Prior probabilities

'empirical' (default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in <i>Y</i> .
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>SVMModel.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure array	A structure <i>S</i> with two fields: <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as <i>Y</i>. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

`fitensemble` normalizes the prior probabilities in `Prior` to sum to 1.

```
Example: struct('ClassNames',
{{'setosa','versicolor','virginica'}}, 'ClassProbs', 1:3)
```

Data Types: char | double | single | struct

'Weights' — Observation weights

numeric vector of positive values | character vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of *X* or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of *X* or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n,1)`, where n is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char`

Sampling Options for Boosting Methods and Bagging

'FResample' — Fraction of training set to resample

1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of `'FResample'` and a positive scalar in (0,1].

To use `'FResample'`, specify `'bag'` for `Method` or set `Resample` to `'on'`.

Example: `'FResample',0.75`

Data Types: `single` | `double`

'Replace' — Flag indicating to sample with replacement

'on' (default) | 'off'

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of `'Replace'` and `'off'` or `'on'`.

- For `'on'`, the software samples the training observations with replacement.
- For `'off'`, the software samples the training observations without replacement. If you set `Resample` to `'on'`, then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set `Method` to `'bag'` or set `Resample` to `'on'`, `Replace` has no effect.

Example: `'Replace','off'`

Data Types: `char`

'Resample' — Flag indicating to resample

'off' | 'on'

Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If `Method` is any boosting method, then:
 - 'Resample', 'on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
 - 'Resample', 'off' specifies to reweight observations at every learning iteration. This setting is the default.
- If `Method` is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see `FResample`) with or without replacement (see `Replace`).

AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, and LSBoost Method Options

'LearnRate' — Learning rate for shrinkage

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate',0.1

Data Types: single | double

RUSBoost Method Options

'LearnRate' — Learning rate for shrinkage

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: `'LearnRate', 0.1`

Data Types: `single` | `double`

'RatioToSmallest' — Sampling proportion with respect to lowest-represented class

positive numeric scalar | numeric vector of positive values

Sampling proportion with respect to the lowest-represented class, specified as the comma-separated pair consisting of `'RatioToSmallest'` and a numeric scalar or numeric vector of positive values with length equal to the number of distinct classes in the training data.

Suppose that there are K classes in the training data and the lowest-represented class has m observations in the training data.

- If you specify the positive numeric scalar s , then `fitensemble` samples $s*m$ observations from each class, that is, it uses the same sampling proportion for each class. For more details, see “Algorithms” on page 29-2434.
- If you specify the numeric vector $[s_1, s_2, \dots, s_K]$, then `fitensemble` samples s_i*m observations from class i , $i = 1, \dots, K$. The elements of `RatioToSmallest` correspond to the order of the class names specified using `ClassNames` (see “Tips” on page 29-2432).

The default value is `ones(K, 1)`, which specifies to sample m observations from each class.

Example: `'RatioToSmallest', [2, 1]`

Data Types: `single` | `double`

LPBoost and TotalBoost Method Options

'MarginPrecision' — Margin precision to control convergence speed

0.1 (default) | numeric scalar in $[0, 1]$

Margin precision to control convergence speed, specified as the comma-separated pair consisting of `'MarginPrecision'` and a numeric scalar in the interval $[0, 1]$. `MarginPrecision` affects the number of boosting iterations required for convergence.

Tip: To train an ensemble using many learners, specify a small value for `MarginPrecision`. For training using a few learners, specify a large value.

Example: `'MarginPrecision',0.5`

Data Types: `single` | `double`

RobustBoost Method Options

'RobustErrorGoal' — Target classification error

0.1 (default) | nonnegative numeric scalar

Target classification error, specified as the comma-separated pair consisting of `'RobustErrorGoal'` and a nonnegative numeric scalar. The upper bound on possible values depends on the values of `RobustMarginSigma` and `RobustMaxMargin`. However, the upper bound cannot exceed 1.

Tip: For a particular training set, usually there is an optimal range for `RobustErrorGoal`. If you set it too low or too high, then the software can produce a model with poor classification accuracy. Try cross-validating to search for the appropriate value.

Example: `'RobustErrorGoal',0.05`

Data Types: `single` | `double`

'RobustMarginSigma' — Classification margin distribution spread

0.1 (default) | positive numeric scalar

Classification margin distribution spread over the training data, specified as the comma-separated pair consisting of `'RobustMarginSigma'` and a positive numeric scalar. Before specifying `RobustMarginSigma`, consult the literature on `RobustBoost`, for example, [19].

Example: `'RobustMarginSigma',0.5`

Data Types: `single` | `double`

'RobustMaxMargin' — Maximal classification margin

0 (default) | nonnegative numeric scalar

Maximal classification margin in the training data, specified as the comma-separated pair consisting of `'RobustMaxMargin'` and a nonnegative numeric scalar. The software minimizes the number of observations in the training data having classification margins below `RobustMaxMargin`.

Example: `'RobustMaxMargin',1`

Data Types: `single` | `double`

Random Subspace Method Options

`'NPredToSample'` — Number of predictors to sample

1 (default) | positive integer

Number of predictors to sample for each random subspace learner, specified as the comma-separated pair consisting of `'NPredToSample'` and a positive integer in the interval $1, \dots, p$, where p is the number of predictor variables (`size(X,2)` or `size(Tbl,2)`).

Data Types: `single` | `double`

Output Arguments

Mdl1 — Trained ensemble model

`ClassificationBaggedEnsemble` model object | `ClassificationEnsemble` model object | `ClassificationPartitionedEnsemble` cross-validated model object | `RegressionBaggedEnsemble` model object | `RegressionEnsemble` model object | `RegressionPartitionedEnsemble` cross-validated model object

Trained ensemble model, returned as one of the model objects in this table.

Model Object	Type Setting	Specify Any Cross-Validation Options?	Method Setting	Resample Setting
<code>ClassificationBaggedEnsemble</code>	<code>'classification'</code>	No	<code>'Bag'</code>	<code>'on'</code>
<code>ClassificationEnsemble</code>	<code>'classification'</code>	No	Any ensemble-aggregation method for classification	<code>'off'</code>

Model Object	Type Setting	Specify Any Cross-Validation Options?	Method Setting	Resample Setting
ClassificationPartit	'classification'	Yes	Any classification ensemble-aggregation method	'off' or 'on'
RegressionBaggedE	'regression'	No	'Bag'	'on'
RegressionEnsembl	'regression'	No	'LSBoost'	'off'
RegressionPartition	'regression'	Yes	'LSBoost' or 'Bag'	'off' or 'on'

The name-value pair arguments that control cross-validation are `CrossVal`, `Holdout`, `KFold`, `Leaveout`, and `CVPartition`.

To reference properties of `Mdl`, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

Tips

- `NLearn` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume` for classification problems, or `resume` for regression problems.
- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.
- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.
- In classification problems (that is, `Type` is 'classification'):
 - If the ensemble-aggregation method (`Method`) is 'bag' and:

- The misclassification cost (**Cost**) is highly imbalanced, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty.
- The class prior probabilities (**Prior**) are highly skewed, the software oversamples unique observations from the class that has a large prior probability.

For smaller sample sizes, these combinations can result in a low relative frequency of out-of-bag observations from the class that has a large penalty or prior probability. Consequently, the estimated out-of-bag error is highly variable and it can be difficult to interpret. To avoid large estimated out-of-bag error variances, particularly for small sample sizes, set a more balanced misclassification cost matrix using **Cost** or a less skewed prior probability vector using **Prior**.

- Because the order of some input and output arguments correspond to the distinct classes in the training data, it is good practice to specify the class order using the **ClassNames** name-value pair argument.
 - To determine the class order quickly, remove all observations from the training data that are unclassified (that is, have a missing label), obtain and display an array of all the distinct classes, and then specify the array for **ClassNames**. For example, suppose the response variable (**Y**) is a cell array of labels. This code specifies the class order in the variable **classNames**.

```
Ycat = categorical(Y);
classNames = categories(Ycat)
categorical assigns <undefined> to unclassified observations and
categories excludes <undefined> from its output. Therefore, if you use this
code for cell arrays of labels or similar code for categorical arrays, then you
do not have to remove observations with missing labels to obtain a list of the
distinct classes.
```

- To specify that the class order from lowest-represented label to most-represented, then quickly determine the class order (as in the previous bullet), but arrange the classes in the list by frequency before passing the list to **ClassNames**. Following from the previous example, this code specifies the class order from lowest- to most-represented in **classNamesLH**.

```
Ycat = categorical(Y);
classNames = categories(Ycat);
freq = countcats(Ycat);
```

```
[~,idx] = sort(freq);  
classNamesLH = classNames(idx);
```

Algorithms

- For details of ensemble-aggregation algorithms, see “Ensemble Algorithms” on page 18-169.
- If you specify `Method` to be a boosting algorithm and `Learners` to be decision trees, then the software grows *stumps* by default. A decision stump is one root node connected to two terminal, leaf nodes. You can adjust tree depth by specifying the `MaxNumSplits`, `MinLeafSize`, and `MinParentSize` name-value pair arguments using `templateTree`.
- `fitensemble` generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class can be low. Therefore, the estimated out-of-bag error can have a large variance and can be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.
- For the RUSBoost ensemble-aggregation method (`Method`), the name-value pair argument `RatioToSmallest` specifies the sampling proportion for each class with respect to the lowest-represented class. For example, suppose that there are two classes in the training data: *A* and *B*. *A* have 100 observations and *B* have 10 observations. and that the lowest-represented class has *m* observations in the training data.
 - If you set `'RatioToSmallest',2`, then $s*m = 2*10 = 20$. Consequently, `fitensemble` trains every learner using 20 observations from class *A* and 20 observations from class *B*. If you set `'RatioToSmallest',[2 2]`, then you obtain the same result.
 - If you set `'RatioToSmallest',[2,1]`, then $s1*m = 2*10 = 20$ and $s2*m = 1*10 = 10$. Consequently, `fitensemble` trains every learner using 20 observations from class *A* and 10 observations from class *B*.
- For ensembles of decision trees, and for dual-core systems and above, `fitensemble` parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

Introduced in R2011a

fitnlm

Fit nonlinear regression model

Syntax

```
mdl = fitnlm(tbl,modelfun,beta0)
mdl = fitnlm(X,y,modelfun,beta0)
mdl = fitnlm( ____,modelfun,beta0,Name,Value)
```

Description

`mdl = fitnlm(tbl,modelfun,beta0)` fits the model specified by `modelfun` to variables in the table or dataset array `tbl`, and returns the nonlinear model `mdl`.

`fitnlm` estimates model coefficients using an iterative procedure starting from the initial values in `beta0`.

`mdl = fitnlm(X,y,modelfun,beta0)` fits a nonlinear regression model using the column vector `y` as a response variable and the columns of the matrix `X` as predictor variables.

`mdl = fitnlm(____,modelfun,beta0,Name,Value)` fits a nonlinear regression model with additional options specified by one or more `Name, Value` pair arguments.

Examples

Nonlinear Model from Table

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(tbl,modelfun,beta0)
```

```
mdl =
```

```
Nonlinear regression model:
```

```
MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

```
Number of observations: 392, Error degrees of freedom: 387
```

```
Root Mean Squared Error: 3.96
```

```
R-Squared: 0.745, Adjusted R-Squared 0.743
```

```
F-statistic vs. constant model: 283, p-value = 1.79e-113
```

Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)
```

```
mdl =
```

```
Nonlinear regression model:
```

```
y ~ b1 + b2*x1^b3 + b4*x2^b5
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387
 Root Mean Squared Error: 3.96
 R-Squared: 0.745, Adjusted R-Squared 0.743
 F-statistic vs. constant model: 283, p-value = 1.79e-113

Adjust Fitting Options in Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Strive for more accuracy by lowering the `TolFun` option, and observe the iterations by setting the `Display` option.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
```

Create options to lower `TolFun` and to report iterative display, and create a model using the options.

```
opts = statset('Display','iter','TolFun',1e-10);
mdl = fitnlm(X,y,modelfun,beta0,'Options',opts);
```

Iteration	SSE	Norm of Gradient	Norm of Step

Specify Nonlinear Regression Using Model Name Syntax

Specify a nonlinear regression model for estimation using a function handle or model syntax.

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Use a function handle to specify the Hougen-Watson model for the rate data.

```
mdl = fitnlm(X,y,@hougen,beta0)
```

```
mdl =
```

Nonlinear regression model:

$y \sim \text{hougen}(b,X)$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 0.193

R-Squared: 0.999, Adjusted R-Squared 0.998

F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatively, you can use an expression to specify the Hougen-Watson model for the rate data.

```
myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';
mdl2 = fitnlm(X,y,myfun,beta0)
```

```
mdl2 =
```

Nonlinear regression model:

$y \sim (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654

b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 0.193
R-Squared: 0.999, Adjusted R-Squared 0.998
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Estimate Nonlinear Regression Using Robust Fitting Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp(-b_3 x) + \varepsilon,$$

where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility  
b = [1;3;2];  
x = exprnd(2,100,1);  
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');  
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use an expression to specify the model.

```
b0 = [2;2;2];  
modelstr = 'y ~ b1 + b2*exp(-b3*x)';  
mdl = fitnlm(x,y,modelstr,b0,'Options',opts)
```

```
mdl =
```

```
Nonlinear regression model (robust fit):  
y ~ b1 + b2*exp( - b3*x)
```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
b1	1.0218	0.07202	14.188	2.1344e-25
b2	3.6619	0.25429	14.401	7.974e-26
b3	2.9732	0.38496	7.7232	1.0346e-11

Number of observations: 100, Error degrees of freedom: 97
 Root Mean Squared Error: 0.501
 R-Squared: 0.807, Adjusted R-Squared 0.803
 F-statistic vs. constant model: 203, p-value = 2.34e-35

Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights)
```

```
mdl =
```

```
Nonlinear regression model:
y ~ hougen(b,X)
```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
	_____	_____	_____	_____

b1	0.83085	0.58224	1.427	0.19142
b2	0.04095	0.029663	1.3805	0.20477
b3	0.025063	0.019673	1.274	0.23842
b4	0.080053	0.057812	1.3847	0.20353
b5	1.8261	1.281	1.4256	0.19183

Number of observations: 13, Error degrees of freedom: 8
 Root Mean Squared Error: 0.037
 R-Squared: 0.998, Adjusted R-Squared 0.998
 F-statistic vs. zero model: 1.14e+03, p-value = 3.49e-11

Nonlinear Regression Model Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
mdl = fitnlm(X,y,@hougen,beta0,'ErrorModel','combined')
```

```
mdl =
```

```
Nonlinear regression model:
y ~ hougen(b,X)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86702	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075158	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8
 Root Mean Squared Error: 1.27
 R-Squared: 0.999, Adjusted R-Squared 0.998

F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. If you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variable must be numeric.

You specify the response and predictor names in your model specification. If you do not specify a model, you can set a different column as the response variable by using the `ResponseVar` name-value pair argument. You can select a subset of the columns as predictors by using the `PredictorVars` name-value pair argument.

Data Types: single | double | logical

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

Data Types: single | double | logical

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: single | double

modelfun — Functional form of the model

function handle | character vector of the form `'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'`

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
 - `b` is a coefficient vector with the same number of elements as `beta0`.
 - `x` is a matrix with the same number of columns as `X` or the number of predictor variable columns of `tbl`.

`modelfun(b,x)` returns a column vector that contains the same number of rows as `x`. Each row of the vector is the result of evaluating `modelfun` on the corresponding row of `x`. In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. `modelfun` should return real numbers to obtain meaningful coefficients.

- Character vector of the form `'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'`, where `f` represents a scalar function of the scalar coefficient variables `b1,...,bj` and the scalar data variables `x1,...,xk`.

beta0 — Coefficients

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. `NonLinearModel` starts its search for optimal coefficients from `beta0`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'ErrorModel','combined','Exclude',2,'Options',opt` specifies the error model as the combined model, excludes the second observation from the fit, and uses the options defined in the structure `opt` to control the iterative fitting procedure.

'CoefficientNames' — Names of the model coefficients

`{'b1','b2',...,'bk'}` (default) | cell array of character vectors

Names of the model coefficients, specified as a cell array of character vectors.

Data Types: `char`

'ErrorModel' — Form of the error variance model

'constant' (default) | 'proportional' | 'combined'

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f , and one or two parameters a and b

'constant' (default)	$y = f + ae$
'proportional'	$y = f + bfe$
'combined'	$y = f + (a + b f)e$

The only allowed error model when using `Weights` is 'constant'.

Note: `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

Example: 'ErrorModel', 'proportional'

'ErrorParameters' — Initial estimates of the error model parameters

numeric array

Initial estimates of the error model parameters for the chosen `ErrorModel`, specified as a numeric array.

Error Model	Parameters	Default Values
'constant'	a	1
'proportional'	b	1
'combined'	a, b	[1, 1]

You can only use the 'constant' error model when using `Weights`.

Note: `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for a and the starting value 2 for b as follows.

Example: 'ErrorParameters', [1,2]

Data Types: single | double

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

'Options' — Options for controlling the iterative fitting procedure

[] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by `statset`. The relevant fields are the nonempty fields in the structure returned by the call `statset('fitnlm')`.

Option	Meaning	Default
DerivStep	Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.	$\text{eps}^{(1/3)}$
Display	Amount of information displayed by the fitting algorithm. <ul style="list-style-type: none"> 'off' — Displays no information. 'final' — Displays the final output. 	'off'

Option	Meaning	Default
	<ul style="list-style-type: none"> 'iter' — Displays iterative output to the Command Window. 	
FunValCheck	Character vector indicating to check for invalid values, such as NaN or Inf, from the model function.	'on'
MaxIter	Maximum number of iterations allowed. Positive integer.	200
RobustWgtFun	Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 29-2453	[]
Tune	Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.	See “Robust Options” on page 29-2453 for the default, which depends on RobustWgtFun.
TolFun	Termination tolerance for the objective function value. Positive scalar.	1e-8
TolX	Termination tolerance for the parameters. Positive scalar.	1e-8

Data Types: struct

'PredictorVars' — Predictor variables

cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The character vectors should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

```
Example: 'PredictorVars', [2,3]
```

```
Example: 'PredictorVars', logical([0 1 1 0 0 0])
```

Data Types: `single` | `double` | `logical` | `cell`

'ResponseVar' — Response variable

last column of `tbl` (default) | variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable.

If you specify a model, it specifies the response variable. Otherwise, when fitting a table or dataset array, 'ResponseVar' indicates which variable `fitnlm` should use as the response.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

```
Example: 'ResponseVar', 'yield'
```

```
Example: 'ResponseVar', [4]
```

```
Example: 'ResponseVar', logical([0 0 0 1 0 0])
```

Data Types: `single` | `double` | `logical` | `char`

'VarNames' — Names of variables in fit

{'x1', 'x2', ..., 'xn', 'y'} (default) | cell array of character vectors

Names of variables in fit, specified as the comma-separated pair consisting of 'VarNames' and a cell array of character vectors including the names for the columns of `X` first, and the name for the response variable `y` last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

```
Example: 'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}
```

Data Types: `cell`

'Weights' — Observation weights

`ones(n,1)` (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have n elements, where n is the number of rows in `tbl` or `y`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `NonLinearModel` estimates the error variance at observation `i` by $\text{MSE} * (1/W(i))$, where `MSE` is the mean squared error.

Data Types: `single` | `double` | `function_handle`

Output Arguments

`mdl` — Nonlinear model

`NonLinearModel` object

Nonlinear model representing a least-squares fit of the response to the data, returned as a `NonLinearModel` object.

If the `Options` structure contains a nonempty `RobustWgtFun` field, the model is not a least-squares fit, but uses the `RobustWgtFun` robust fitting function.

For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

Definitions

Robust Options

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339

LinearMixedModel.fitmatrix

Class: LinearMixedModel

Fit linear mixed-effects model using design matrices

Compatibility

LinearMixedModel.fitmatrix will be removed in a future release. Use fitlmematrix instead.

Syntax

```
lme = LinearMixedModel.fitmatrix(X,y,Z,[])  
lme = LinearMixedModel.fitmatrix(X,y,Z,G)  
lme = LinearMixedModel.fitmatrix( ____,Name,Value)
```

Description

`lme = LinearMixedModel.fitmatrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where `n` is the number of observations. Using `LinearMixedModel.fitmatrix(X,Y,Z,[])` without a specified covariance pattern most likely will result in a non-identifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using 'CovariancePattern' name-value pair argument.

`lme = LinearMixedModel.fitmatrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = LinearMixedModel.fitmatrix(____,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

Input Arguments

X — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of **X** corresponds to one observation, and each column of **X** corresponds to one variable.

Data Types: `single` | `double`

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then **Z** must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then **Z** must be a cell array of length *R*. Each cell of **Z** contains an *n*-by-*q*(*r*) design matrix $Z\{r\}$, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, $Z\{r\}$.

Data Types: `single` | `double` | `cell`

G — Grouping variable or variables

n-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then **G** must be an n -by-1 vector corresponding to a single grouping variable with M levels or groups.

G can be a categorical vector, numeric vector, character array, or cell array of character vectors.

- If there are multiple random-effects terms, then **G** must be a cell array of length R . Each cell of **G** contains a grouping variable $G\{r\}$, $r = 1, 2, \dots, R$, with $M(r)$ levels.

$G\{r\}$ can be a categorical vector, numeric vector, character array, or cell array of character vectors.

Data Types: `single` | `double` | `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

'FixedEffectPredictors' — Names of columns in fixed-effects design matrix
{'x1', 'x2', ..., 'xP'} (default) | cell array of length p

Names of columns in the fixed-effects design matrix X , specified as the comma-separated pair consisting of **'FixedEffectPredictors'** and a cell array of length p .

For example, if you have a constant term and two predictors, say **TimeSpent** and **Gender**, where **Female** is the reference level for **Gender**, as the fixed effects, then you can specify the names of your fixed effects in the following way. **Gender_Male** represents the dummy variable you must create for category **Male**. You can choose different names for these variables.

Example: **'FixedEffectPredictors'**,
{'Intercept', 'TimeSpent', 'Gender_Male'},

Data Types: `cell`

'RandomEffectPredictors' — Names of columns in random-effects design matrix or cell array

cell array of length q | cell array of length R with elements of length $q(r)$, $r = 1, 2, \dots, R$

Names of columns in the random-effects design matrix or cell array `Z`, specified as the comma-separated pair consisting of `'RandomEffectPredictors'` and either of the following:

- A cell array of length q when `Z` is an n -by- q design matrix. In this case, the default is `{'z1', 'z2', ..., 'zQ'}`.
- A cell array of length R , when `Z` is a cell array of length R with each element `Z{r}` of length $q(r)$, $r = 1, 2, \dots, R$. In this case, the default is `{'z11', 'z12', ..., 'z1Q(1)'}, ..., {'zr1', 'zr2', ..., 'zrQ(r)'}`.

For example, suppose you have correlated random effects for intercept and a variable named `Acceleration`. Then, you can specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {'Intercept', 'Acceleration'}`

If you have two random effects terms, one for the intercept and the variable `Acceleration` grouped by variable `g1`, and the second for the intercept, grouped by the variable `g2`, then you specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {'Intercept', 'Acceleration'}, {'Intercept'}`

Data Types: `cell`

'ResponseVarName' — Name of response variable

`'y'` (default) | character vector

Name of response variable, specified as the comma-separated pair consisting of `'ResponseVarName'` and a character vector.

For example, if your response variable name is `score`, then you can specify it as follows.

Example: `'ResponseVarName', 'score'`

Data Types: `char`

'RandomEffectGroups' — Names of random effects grouping variables

`'g'` or `{'g1', 'g2', ..., 'gR'}` (default) | character vector | cell array of character vectors

Names of random effects grouping variables, specified as the comma-separated pair `'RandomEffectGroups'` and either of the following:

- Character vector — If there is only one random-effects term, that is, if **G** is a vector, then the value of `'RandomEffectGroups'` is a character vector containing the name for the grouping variable **G**. The default is `'g'`.
- Cell array of character vectors — If there are multiple random-effects terms, that is, if **G** is a cell array of length *R*, then the value of `'RandomEffectGroups'` is a cell array of length *R*, where each cell contains the name for the grouping variable **G**{*r*}. The default is `{'g1', 'g2', ..., 'gR'}`.

For example, if you have two random-effects terms, **z1** and **z2**, grouped by the grouping variables **sex** and **subject**, then you can specify the names of your grouping variables as follows.

Example: `'RandomEffectGroups', {'sex', 'subject'}`

Data Types: `char` | `cell`

'CovariancePattern' — Pattern of covariance matrix

`'FullCholesky'` (default) | character vector | square symmetric logical matrix | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of `'CovariancePattern'` and a character vector, a square symmetric logical matrix, or a cell array of character vectors or logical matrices.

If there are *R* random-effects terms, then the value of `'CovariancePattern'` must be a cell array of length *R*, where each element *r* of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the *r*th random-effects term. The options for each element follow.

`'FullCholesky'`

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

`'Full'`

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

`'Diagonal'`

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

`'CompSymm'`

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

`PAT`

Square symmetric logical matrix. If `'CovariancePattern'` is defined by the matrix `PAT`, and if `PAT(a,b) = false`, then the `(a,b)` element of the corresponding covariance matrix is constrained to be 0.

Example: `'CovariancePattern', 'Diagonal'`

Example: `'CovariancePattern', {'Full', 'Diagonal'}`

'FitMethod' — Method for estimating parameters

`'ML'` (default) | `'REML'`

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of `'FitMethod'` and either of the following.

`'ML'`

Default. Maximum likelihood estimation

`'REML'`

Restricted maximum likelihood estimation

Example: `'FitMethod', 'REML'`

'Weights' — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n , where n is the number of observations.

Data Types: `single` | `double`**'Exclude' — Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude', [13,67]`Data Types: `single` | `double` | `logical`**'DummyVarCoding' — Coding to use for dummy variables**`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the following.

Value	Description
<code>'reference'</code>	Default. Coefficient for first category set to 0.
<code>'effects'</code>	Coefficients sum to 0.
<code>'full'</code>	One dummy variable for each category.

Example: `'DummyVarCoding', 'effects'`**'Optimizer' — Optimization algorithm**`'quasinevton'` (default) | `'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

'quasinevton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminunc'

'OptimizerOptions' — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasinevton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasinevton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

'ToIFun' — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

'ToIX' — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

'MaxIter' — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

'Display' — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

'StartMethod' — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

Value	Description
'default'	An internally defined default value
'random'	A random initial value

Example: 'StartMethod', 'random'

'Verbose' — Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose', true

'CheckHessian' — Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian', true

Output Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

Examples

No Grouping Variable Specified

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, where MPG is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```
y = MPG;  
X = [ones(size(Weight)), Weight];
```

```
Z = ones(size(y));
lme = LinearMixedModel.fitmatrix(X,y,Z,Model_Year)
```

```
lme =
```

```

Longitudinal Study with Covariate

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six two-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\ + \beta_6 (\text{Week}_i * I[\text{PB}]_i) + \beta_7 (\text{Week}_i * I[\text{PC}]_i) + \beta_8 (\text{Week}_i * I[\text{PD}]_i) \\ + b_{0m} + b_{1m} \text{Week}_{im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. `IW` stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[\text{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
X = [ones(120,1), InitialWeight, D(:,2:4), Week, ...
     D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;
```

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G, 'FixedEffectPredictors',...
{'Intercept', 'InitWeight', 'PrgB', 'PrgC', 'PrgD', 'Week', 'Week_PrgB', 'Week_PrgC', 'Week_PrgD',
'RandomEffectPredictors', {{'Intercept', 'Week'}}, 'RandomEffectGroups', {'Subject'})
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:

The P -values 0.0228 and 0.0115 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects that are in program B is significantly different relative to the weight loss of subjects that are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the `compare` method.

Random-Intercept Model

Load the sample data.

```
load flu
```

`flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into an array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by Date. The corresponding model is

$$y_{im} = \beta_0 + \beta_1 \text{WtdILL}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable Date, b_{0m} is the random effect for level m of the grouping variable Date, and ε_{im} is the observation error for observation i . The random effect has the prior distribution,

$$b_{0m} \sim N(0, \sigma_b^2),$$

and the error term has the distribution,

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
y = flu2.FluRate;
X = [ones(468,1) flu2.WtdILL];
Z = [ones(468,1)];
G = flu2.Date;
```

Fit the linear mixed-effects model.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',{'Intercept','NationalRate'},
                                'RandomEffectPredictors',{'Intercept'},'RandomEffectGroups',{'Date'})
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	468
Fixed effects coefficients	2
Random effects coefficients	52
Covariance parameters	2

```
Formula:
```

```
y ~ Intercept + NationalRate + (Intercept | Date)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
286.24	302.83	-139.12	278.24

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'Intercept'	0.16385	0.057525	2.8484	466	0.0045885
'NationalRate'	0.7236	0.032219	22.459	466	3.0502e-76

Lower	Upper
0.050813	0.27689
0.66028	0.78691

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower
'Intercept'	'Intercept'	'std'	0.17146	0.13227

Upper
0.22226

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits of the standard deviation of the random-effects term σ_b do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using `compare` method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics STATS
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')

y_hat =

    1.4674
```

You can simply display the fitted value using the `fitted(lme)` method.

```
F = fitted(lme);
F(28)

ans =

    1.4674
```

Randomized-Block Design

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'));
```

The data set shows the deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. 'effects' contrasts mean that the coefficients sum to zero. You need to create two contrast coded variables in the fixed-effects design matrix, X1 and X2, where

$$\text{Shift_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

$$\text{Shift_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

The model corresponds to

$$\begin{aligned} \text{Morning Shift:} \quad \text{QCDev}_{im} &= \beta_0 + \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im}, \\ \text{Evening Shift:} \quad \text{QCDev}_{im} &= \beta_0 + \beta_1 \text{Shift_Evening}_i + b_{0m} + \epsilon_{im}, \\ \text{Night Shift:} \quad \text{QCDev}_{im} &= \beta_0 - \beta_1 \text{Shift_Evening}_i - \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im}, \end{aligned}$$

where i represents the observations, and m represents the operators, $i = 1, 2, \dots, 15$, and $m = 1, 2, \dots, 5$. The random effects and the observation error have the following distributions:

$$b_{0m} \sim N(0, \sigma_b^2)$$

and

$$\epsilon_{im} \sim N(0, \sigma^2).$$

```
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
y = shift.QCDev;
Z = ones(15,1);
G = shift.Operator;
```

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FitMethod','REML','FixedEffectPredictors',...
{'Intercept','S_Morning','S_Evening'},'RandomEffectPredictors',{{'Intercept'}},...
'RandomEffectGroups',{'Operator'},'DummyVarCoding','effects')
```

```
lme =
```

```
Linear mixed-effects model fit by REML
```

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

`B = randomEffects(lme)`

```
B =
    0.5775
    1.1757
   -2.1715
    2.3655
   -1.9472
```

The estimated deviation from the target quality characteristics for the third operator working in the evening shift is

$$\begin{aligned}\hat{y}_{\text{Evening,Operator3}} &= \hat{\beta}_0 + \hat{\beta}_1 \text{Shift_Evening} + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value in the following way.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans =
    0.9481
```

Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and the cylinders, and uncorrelated random-effect for intercept and acceleration grouped by the model year. This model corresponds to

$$\text{MPG}_{im} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{HP} + b_{0m} + b_{1m} \text{Acc}_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2),$$

$$b_{1m} \sim N(0, \sigma_1^2),$$

where m represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};
Model_Year = nominal(Model_Year);
```

Now, fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables.

```
lme = LinearMixedModel.fitmatrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{'Model_Year','Model_Year'})
```

```

'Res Std'	3.6874	3.4298	3.9644

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. You can compare these two models using the `compare` (`LinearMixedModel`) method.

Specify the Covariance Pattern

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six two-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables.

```
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week are the fixed effects.

```
D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\ + b_{0m} + b_{1m} \text{Week}_{2im} + b_{2m} \text{Week}_{4im} + b_{3m} \text{Week}_{6im} + b_{4m} \text{Week}_{8im} \\ + b_{5m} \text{Week}_{10im} + b_{6m} \text{Week}_{12im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$.

β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. `IW` stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For

example, $I[\text{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

Fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week'},...
'RandomEffectPredictors',{{'Intercept','Week'}},...
'RandomEffectGroups',{'Subject'},'CovariancePattern','Isotropic')
```

Definitions

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Tips

- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix`.

Alternatives

You can also fit a linear mixed-effects model using `fitlme(tbl, formula)`, where `tbl` is a table or dataset array containing the response `y`, the predictor variables `X`, and the grouping variables, and `formula` is of the form `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`.

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

`fitlme` | `LinearMixedModel`

fitNaiveBayes

(to be removed) Train naive Bayes classifier

Compatibility

`fitNaiveBayes` will be removed in a future release. Use `fitcnb` instead.

Syntax

```
NBModel = fitNaiveBayes(X,Y)
NBModel = fitNaiveBayes(X,Y,Name,Value)
```

Description

`NBModel = fitNaiveBayes(X,Y)` returns a naive Bayes classifier `NBModel`, trained by predictors `X` and class labels `Y` for K -level classification.

Predict labels for new data by passing the data and `NBModel` to `predict`.

`NBModel = fitNaiveBayes(X,Y,Name,Value)` returns a naive Bayes classifier with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify a distribution to model the data, prior probabilities for the classes, or the kernel smoothing window bandwidth.

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of `Y` and the number of rows of `X` must be equivalent.

Data Types: `double`

Y – Class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Class labels to which the naive Bayes classifier is trained, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Each element of `Y` defines the class membership of the corresponding row of `X`. `Y` supports K class levels.

If `Y` is a character array, then each row must correspond to one class label.

The length of `Y` and the number of rows of `X` must be equivalent.

Data Types: `cell` | `char` | `double` | `logical`

Note: The software treats NaN, empty character vector (' '), and <undefined> elements as missing values.

- If `Y` contains missing values, then the software removes them and the corresponding rows of `X`.
- If `X` contains any rows composed entirely of missing values, then the software removes those rows and the corresponding elements of `Y`.
- If `X` contains missing values and you set '`Distribution`', '`mn`', then the software removes those rows of `X` and the corresponding elements of `Y`.
- If a predictor is not represented in a class, that is, if all of its values are NaN within a class, then the software returns an error.

Removing rows of `X` and corresponding elements of `Y` decreases the effective training or cross-validation sample size.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'Distribution','mn','Prior','uniform','KSWidth',0.5` specifies the following: the data distribution is multinomial, the prior probabilities for all classes are equal, and the kernel smoothing window bandwidth for all classes is 0.5 units.

'Distribution' — Data distributions

`'normal'` (default) | `'kernel'` | `'mn'` | `'mvmn'` | cell array of character vectors

Data distributions `fitNaiveBayes` uses to model the data, specified as the comma-separated pair consisting of `'Distribution'` and `'kernel'`, `'mn'`, `'mvmn'`, `'normal'`, or a cell array of character vectors.

This table summarizes the available distributions.

Value	Description
<code>'kernel'</code>	Kernel smoothing density estimate.
<code>'mn'</code>	Multinomial distribution. If you specify <code>mn</code> , then all features are components of a multinomial distribution. Therefore, you cannot include <code>'mn'</code> as an element of a cell array of character vectors. For details, see “Algorithms” on page 29-2493.
<code>'mvmn'</code>	Multivariate multinomial distribution. For details, see “Algorithms” on page 29-2493.
<code>'normal'</code>	Normal (Gaussian) distribution.

If you specify a character vector, then the software models all the features using that distribution. If you specify a 1-by- D cell array of character vectors, then the software models feature j using the distribution in element j of the cell array.

Example: `'Distribution',{'kernel','normal'}`

Data Types: `cell` | `char`

'KSSupport' — Kernel smoothing density support

`'unbounded'` (default) | `'positive'` | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of `'KSSupport'` and a numeric row vector, `'positive'`, `'unbounded'`, or a cell array. The software applies the kernel smoothing density to this region.

If you do not specify 'Distribution', 'kernel', then the software ignores the values of 'KSSupport', 'KSType', and 'KSWidth'.

This table summarizes the available options for setting the kernel smoothing density region.

Value	Description
1-by-2 numeric row vector	For example, [L,U], where L and U are the finite lower and upper bounds, respectively, for the density support.
'positive'	The density support is all positive real values.
'unbounded'	The density support is all real values.

If you specify a 1-by- D cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel support in cell j for feature j in X .

Example: 'KSSupport', {[-10,20], 'unbounded' }

Data Types: cell | char | double

'KSType' — Kernel smoother type

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | cell array of character vectors

Kernel smoother type, specified as the comma-separated pair consisting of 'KSType' and 'box', 'epanechnikov', 'normal', 'triangle', or a cell array of character vectors.

If you do not specify 'Distribution', 'kernel', then the software ignores the values of 'KSSupport', 'KSType', and 'KSWidth'.

This table summarizes the available options for setting the kernel smoothing density region. Let $I\{u\}$ denote the indicator function.

Value	Kernel	Formula
'box'	Box (uniform)	$f(x) = 0.5I\{ x \leq 1\}$
'epanechni	Epanechnikov	$f(x) = 0.75(1 - x^2)I\{ x \leq 1\}$
'normal'	Gaussian	$f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2)$

Value	Kernel	Formula
'triangle'	Triangular	$f(x) = (1 - x)I\{ x \leq 1\}$

If you specify a 1-by- D cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel smoother type in cell j for feature j in X .

Example: 'KSType', {'epanechnikov', 'normal'}

Data Types: cell | char

'KSWidth' — Kernel smoothing window bandwidth

matrix of numeric values (default) | numeric column vector | numeric row vector | scalar | structure array

Kernel smoothing window bandwidth, specified as the comma-separated pair consisting of 'KSWidth' and a matrix of numeric values, numeric row vector, numeric column vector, scalar, or structure array.

If you do not specify 'Distribution', 'kernel', then the software ignores the values of 'KSSupport', 'KSType', and 'KSWidth'.

Suppose there are K class levels and D predictors. This table summarizes the available options for setting the kernel smoothing window bandwidth.

Value	Description
K -by- D matrix of numeric values	Element (k,d) specifies the bandwidth for predictor d in class k .
K -by-1 numeric column vector	Element k specifies the bandwidth for all predictors in class k .
1-by- D numeric row vector	Element d specifies the bandwidth in all class levels for predictor d .
scalar	Specifies the bandwidth for all features in all classes.
structure array	A structure array S containing class levels and their bandwidths. S must have two fields: <ul style="list-style-type: none"> $S.width$: A numeric row vector of bandwidths, or a matrix of numeric values with D columns.

Value	Description
	<ul style="list-style-type: none"> S.group: A vector of the same type as <code>Y</code>, containing unique class levels indicating the class for the corresponding element of <code>S.width</code>.

By default, the software selects a default bandwidth automatically for each combination of feature and class by using a value that is optimal for a Gaussian distribution.

Example: `'KSWidth', struct('width', [0.5, 0.25], 'group', {'b'; 'g'})`

Data Types: double | struct

'Prior' — Class prior probabilities

'empirical' (default) | 'uniform' | numeric vector | structure array

Class prior probabilities, specified as the comma-separated pair consisting of 'Prior' and a numeric vector, structure array, 'uniform', or 'empirical'.

This table summarizes the available options for setting prior probabilities.

Value	Description
'empirical'	The software uses the class relative frequencies distribution for the prior probabilities.
numeric vector	<p>A numeric vector of length K specifying the prior probabilities for each class. The order of the elements of <code>Prior</code> should correspond to the order of the class levels. For details on the order of the classes, see “Algorithms” on page 29-2493.</p> <p>The software normalizes prior probabilities to sum to 1.</p>
structure array	<p>A structure array <code>S</code> containing class levels and their prior probabilities. <code>S</code> must have two fields:</p> <ul style="list-style-type: none"> S.prob: A numeric vector of prior probabilities. The software normalizes prior probabilities to sum to 1. S.group: A vector of the same type as <code>Y</code> containing unique class levels indicating the class for the corresponding element of <code>S.prob</code>. <code>S.class</code> must contain all the K levels in <code>Y</code>. It can also contain classes that do not appear in <code>Y</code>. This can be useful if <code>X</code> is a subset of a larger training set. The software ignores any classes that appear in <code>S.group</code> but not in <code>Y</code>.

Value	Description
'uniform'	The prior probabilities are equal for all classes.

Example: `'Prior', struct('prob',[1,2], 'group', {{'b'; 'g'}})`

Data Types: char | double | struct

Output Arguments

NBModel1 — Trained naive Bayes classifier

NaiveBayes classifier

Trained naive Bayes classifier, returned as a NaiveBayes classifier.

Definitions

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor j is the nonnegative number of occurrences of token j in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

Tips

- For classifying count-based data, such as the bag-of-tokens model, use the multinomial distribution (e.g., set `'Distribution', 'mn'`).
- This list defines the order of the classes. It is useful when you specify prior probabilities by setting `'Prior', prior`, where `prior` is a numeric vector.
 - If Y is a categorical array, then the order of the class levels matches the output of `categories(Y)`.
 - If Y is a numeric or logical vector, then the order of the class levels matches the output of `sort(unique(Y))`.
 - For cell arrays of character vectors and character arrays, the order of the class labels is the order which each label appears in Y .

Algorithms

- If you specify 'Distribution', 'mn', then the software considers each observation as multiple trials of a multinomial distribution, and considers each occurrence of a token as one trial (see “Bag-of-Tokens Model” on page 29-2492).
- If you specify 'Distribution', 'mvmn', then the software assumes each individual predictor follows a multinomial model within a class. The parameters for a predictor include the probabilities of all possible values that the corresponding feature can take.

Topics

“Naive Bayes Classification” on page 17-38

“Grouping Variables” on page 2-58

Introduced in R2014a

fitPosterior

Class: ClassificationSVM

Fit posterior probabilities

Syntax

```
ScoreSVMModel = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)
```

Description

`ScoreSVMModel = fitPosterior(SVMModel)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMModel`, and by conducting 10-fold cross validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`) as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function on page 29-2516.
- If the classes are perfectly separable, then the transformation function is the step function on page 29-2516.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 29-2630. `fitPosterior` is not appropriate for one-class learning.
- The software stores the optimal score transformation function in `ScoreSVMModel.ScoreTransform`.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)` additionally returns the optimal score-to-posterior-probability transformation function parameters (`ScoreTransform`).

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)`
 returns the optimal score-to-posterior-probability transformation function and its parameters with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

SVMModel — Trained SVM classifier

ClassificationSVM classifier

Trained SVM classifier, specified as a ClassificationSVM.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'CVPartition' — Cross-validation partition

`[]` (default) | `cvpartition` partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition as created by `cvpartition`. You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

`crossval` splits the data into subsets using `cvpartition`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1.

You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Example: `'KFold',8`

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross validation to compute the transformation function, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. Use leave-one-out cross validation by using `'on'`.

You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Example: `'Leaveout','on'`

Output Arguments

ScoreSVMModel — Trained SVM classifier

`ClassificationSVM` classifier

Trained SVM classifier containing the estimated score-to-posterior-probability transformation function, returned as a `ClassificationSVM` classifier.

To estimate posterior probabilities for the training set observations, pass `ScoreSVMModel` to `resubPredict`.

To estimate posterior probabilities for new observations, then pass them and `ScoreSVMModel` to `predict`. If you set `'Standardize',true` in `fitcsvm` to train

`SVMMModel`, then `predict` standardizes the columns of X using the corresponding means in `SVMMModel.Mu` and standard deviations in `SVMMModel.Sigma`.

ScoreTransform — Optimal score transformation function parameters

structure array

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If field `Type` is `sigmoid`, then `ScoreTransform` has the following other fields:
 - **Slope:** The value of A in the sigmoid function on page 29-2516
 - **Intercept:** The value of B in the sigmoid function
- If field `Type` is `step`, then `ScoreTransform` has the following other fields:
 - **PositiveClassProbability:** The value of π in the step function on page 29-2516. It represents the probability that an observation is in the positive class. Also, the posterior probability that an observation is in the positive class given that its score is in the interval `(LowerBound,UpperBound)`.
 - **LowerBound:** The value $\max_{y_n=-1} s_n$ in the step function. It represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score less than `LowerBound` has the posterior probability of being the positive class 0.
 - **UpperBound:** The value $\min_{y_n=+1} s_n$ in the step function. It represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has the posterior probability of being the positive class 1.
- If field `Type` is `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always 1.

Examples

Estimate In-Sample Posterior Probabilities of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X,Y, 'ClassNames', {'b', 'g'}, 'Standardize', true);
```

`SVMModel` is a `ClassificationSVM` classifier. The positive class is `'g'`.

Fit the optimal score-to-posterior-probability transformation function.

```
rng(1); % For reproducibility
ScoreSVMModel = fitPosterior(SVMModel)
```

```
ScoreSVMModel =
```

```
ClassificationSVM
  ResponseName: 'Y'
  CategoricalPredictors: []
    ClassNames: {'b' 'g'}
  ScoreTransform: '@(S)sigmoid(S,-9.481802e-01,-1.218745e-01) '
  NumObservations: 351
    Alpha: [90×1 double]
    Bias: -0.1343
  KernelParameters: [1×1 struct]
    Mu: [1×34 double]
    Sigma: [1×34 double]
  BoxConstraints: [351×1 double]
  ConvergenceInfo: [1×1 struct]
  IsSupportVector: [351×1 logical]
  Solver: 'SMO'
```

Since the classes are inseparable, the score transformation function (`ScoreSVMModel.ScoreTransform`) is the sigmoid function.

Estimate scores and positive class posterior probabilities for the training data. Display the results for the first 10 observations.

```
[label,scores] = resubPredict(SVMModel);
[~,postProbs] = resubPredict(ScoreSVMModel);
table(Y(1:10),label(1:10),scores(1:10,2),postProbs(1:10,2),'VariableNames',...
      {'TrueLabel','PredictedLabel','Score','PosteriorProbability'})
```

ans =

10×4 table

TrueLabel	PredictedLabel	Score	PosteriorProbability
'g'	'g'	1.4861	0.82215
'b'	'b'	-1.0004	0.30436
'g'	'g'	1.8685	0.86916
'b'	'b'	-2.6458	0.084183
'g'	'g'	1.2805	0.79184
'b'	'b'	-1.4617	0.22028
'g'	'g'	2.1672	0.89814
'b'	'b'	-5.7085	0.0050122
'g'	'g'	2.4797	0.92223
'b'	'b'	-2.7811	0.074805

Plot Posterior Probability Contours for Multiple Classes Using SVM

This example steps through the process of one-versus-all (OVA) classification to train a multiclass SVM classifier, and then plots probability contours for each class. To implement OVA directly, see `fitcecoc`.

Load Fisher's iris data set. Use the petal lengths and widths.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Examine a scatter plot of the data.

```
figure
gscatter(X(:,1),X(:,2),Y);
```

```

title('\bf Scatter Diagram of Iris Measurements');
xlabel('Petal length');
ylabel('Petal width');
legend('Location','Northwest');
axis tight

```

Train three binary SVM classifiers that separate each type of iris from the others. Assume that a radial basis function is an appropriate kernel for each, and allow the algorithm to choose a kernel scale. It is good practice to define the class order.

```

classNames = {'setosa'; 'virginica'; 'versicolor'};
numClasses = size(classNames,1);
inds = cell(3,1); % Preallocation
SVMModel = cell(3,1);

```

```

rng(1); % For reproducibility
for j = 1:numClasses
    inds{j} = strcmp(Y,classNames{j}); % OVA classification
    SVMModel{j} = fitcsvm(X,inds{j},'ClassNames',[false true],...
        'Standardize',true,'KernelFunction','rbf','KernelScale','auto');
end

```

fitcsvm uses a heuristic procedure that involves subsampling to compute the value of the kernel scale.

Fit the optimal score-to-posterior-probability transformation function for each classifier.

```

for j = 1:numClasses
    SVMModel{j} = fitPosterior(SVMModel{j});
end

```

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

Define a grid to plot the posterior probability contours. Estimate the posterior probabilities over the grid for each classifier.

```

d = 0.02;
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...
    min(X(:,2)):d:max(X(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];

```

```

posterior = cell(3,1);
for j = 1:numClasses
    [-,posterior{j}] = predict(SVMModel{j},xGrid);
end

```

For each SVM classifier, plot the posterior probability contour under the scatter plot of the data.

```

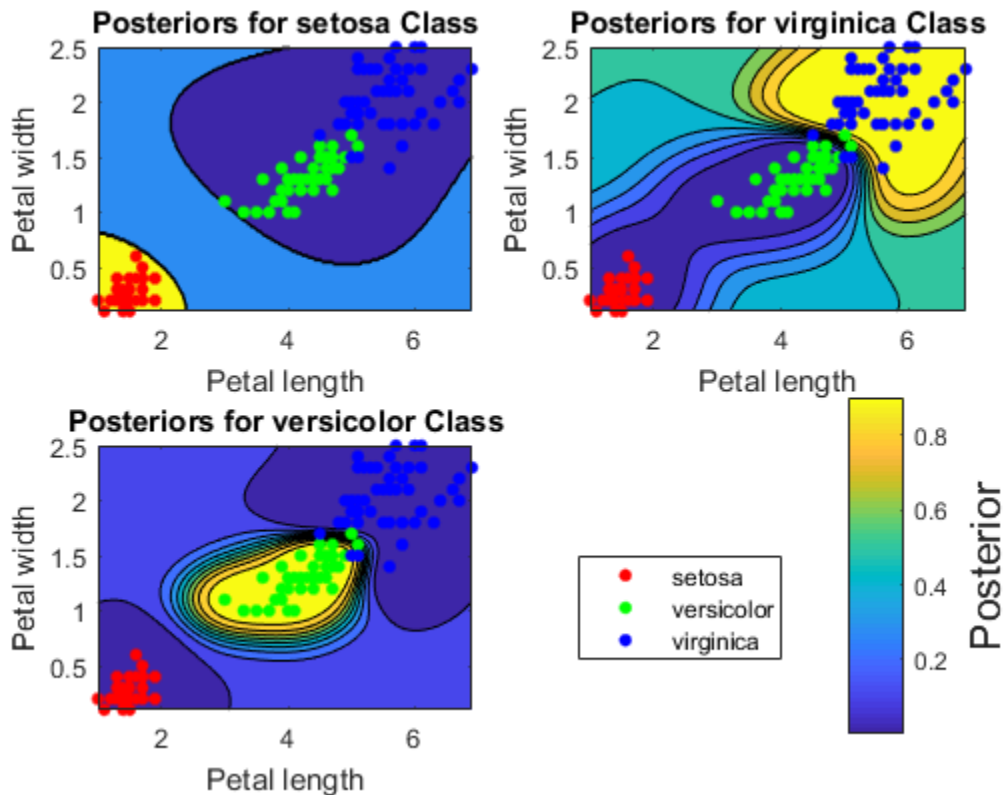

figure
h = zeros(numClasses + 1,1); % Preallocation for graphics handles
for j = 1:numClasses
    subplot(2,2,j)
    contourf(x1Grid,x2Grid,reshape(posterior{j}(:,2),size(x1Grid,1),size(x1Grid,2)));
    hold on
    h(1:numClasses) = gscatter(X(:,1),X(:,2),Y);
    title(sprintf('Posteriors for %s Class',classNames{j}));
    xlabel('Petal length');

```

```

ylabel('Petal width');
legend off
axis tight
hold off
end
h(numClasses + 1) = colorbar('Location','EastOutside',...
    'Position',[0.8,0.1,0.05,0.4]);
set(get(h(numClasses + 1),'YLabel'),'String','Posterior','FontSize',16);
legend(h(1:numClasses),'Location',[0.6,0.2,0.1,0.1]);

```

Fit Optimal Posterior Probability Function Using Holdout Cross Validation

Platt (2000) outlines a bias-reducing method of estimating the score-to-posterior-probability transformation function. This method estimates the transformation function

after the SVM classifier is trained, and uses cross validation to reduce bias. By default, `fitPosterior` and `fitSVMPosterior` use 10-fold cross validation when they estimate the transformation function. To reduce run time for larger data sets, you can specify to use holdout cross validation instead.

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMMModel` is a `ClassificationSVM` classifier. The positive class is `'g'`.

Fit the optimal score-to-posterior-probability transformation function. For comparison, use 10-fold cross validation (default) and specify a 10% holdout test sample.

```
rng(1); % For reproducibility

tic; % Start the stopwatch
SVMMModel_10FCV = fitPosterior(SVMMModel);
toc % Stop the stopwatch and display the run time

tic;
SVMMModel_HO = fitPosterior(SVMMModel,'Holdout',0.10);
toc
```

```
Elapsed time is 1.257017 seconds.
```

```
Elapsed time is 0.275160 seconds.
```

Though both runtimes are short because the data set is relatively small, `SVMMModel_HO` fitted the score transformation function much faster than `SVMMModel_10FCV`.

Definitions

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the output argument `ScoreTransform.Type` is `sigmoid`, then parameters A and B correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- s_j the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the output argument `ScoreTransform.Type` is `step`, then the quantities $\max_{y_k=-1} s_k$

and $\min_{y_k=+1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Tips

Here is one way to predict positive class posterior probabilities.

- 1 Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as, `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.
- 2 Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, for example, `ScoreSVMModel`, is the same, trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- 3 Pass the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) and predictor data matrix to `predict`. The second column of the second output argument stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

Algorithms

If you reestimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to 'none' before estimating the new one

Alternatives

You can also fit the posterior probability function using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad since it accepts a wider range of SVM classifier types.

`ClassificationSVM` | `fitcsvm` | `fitSVMPosterior` | `predict`

fitPosterior

Class: CompactClassificationSVM

Fit posterior probabilities

Syntax

```
ScoreSVMModel = fitPosterior(SVMModel, TBL, Y)
```

```
ScoreSVMModel = fitPosterior(SVMModel, X, Y)
```

```
[ScoreSVMModel, ScoreTransform] = fitPosterior(SVMModel, X, Y)
```

Description

`ScoreSVMModel = fitPosterior(SVMModel, TBL, Y)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning. If you trained `SVMModel` using a table, then you must use a table as input for `fitPosterior`.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMModel`, and by conducting 10-fold cross validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`) as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function on page 29-2516.
- If the classes are perfectly separable, the transformation function is the step function on page 29-2516.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 29-2630. `fitPosterior` is not appropriate for one-class learning.
- The software stores the optimal score-to-posterior-probability transformation function in `ScoreSVMModel.ScoreTransform`.

`ScoreSVMModel = fitPosterior(SVMModel, X, Y)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-

probability transformation function for two-class learning. If you trained `SVMModel` using a matrix, then you must use a matrix as input for `fitPosterior`.

`[ScoreSVMModel, ScoreTransform] = fitPosterior(SVMModel, X, Y)` additionally returns the optimal score-to-posterior-probability transformation function parameters (`ScoreTransform`)

Input Arguments

SVMModel — Trained, compact SVM classifier

`CompactClassificationSVM` classifier

Trained, compact SVM classifier, specified as a `CompactClassificationSVM`.

TBL — Sample data

table

Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. `TBL` must contain all of the predictors used to train `SVMModel`. Optionally, `TBL` can contain an additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `TBL` contains the response variable, you do not need to specify `Y`. If `TBL` does not include the response variable, then the length of `Y` must be equal to the number of rows of `TBL`.

If the sample data used to train `SVMModel` is a table, then you must specify the input data for `fitPosterior` as a table.

Data Types: table

X — Predictor data

matrix

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of `Y` and the number of rows of `X` must be equal.

If you set `'Standardize', true` in `fitcsvm` to train `SVMMODEL`, then the software standardizes the columns of `X` using the corresponding means in `SVMMODEL.MU` and standard deviations in `SVMMODEL.SIGMA`. If the software fits the transformation-function parameter estimates using standardized data, then the estimates might differ from estimation without standardized data.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

If `Y` is a character array, then each element must correspond to one class label.

The length of `Y` and the number of rows of `X` must be equal.

Output Arguments

ScoreSVMMODEL — Trained, compact SVM classifier

`CompactClassificationSVM` classifier

Trained, compact SVM classifier containing the estimated score-to-posterior-probability transformation function, returned as a `CompactClassificationSVM` classifier.

To estimate posterior probabilities, pass `ScoreSVMMODEL` and predictor data to `predict`. If you set `'Standardize', true` in `fitcsvm` to train `SVMMODEL`, then `predict` standardizes the columns of `X` using the corresponding means in `SVMMODEL.MU` and standard deviations in `SVMMODEL.SIGMA`.

ScoreTransform — Optimal score transformation function parameters

structure array

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If field `Type` is `sigmoid`, then `ScoreTransform` has the following other fields:

- **Slope:** The value of A in the sigmoid function on page 29-2516
- **Intercept:** The value of B in the sigmoid function
- If field `Type` is `step`, then `ScoreTransform` has the following other fields:
 - **PositiveClassProbability:** The value of π in the step function on page 29-2516. It represents the probability that an observation is in the positive class. Also, the posterior probability that an observation is in the positive class given that its score is in the interval `(LowerBound,UpperBound)`.
 - **LowerBound:** The value $\max_{y_n=-1} s_n$ in the step function. It represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score less than `LowerBound` has the posterior probability of being the positive class 0.
 - **UpperBound:** The value $\min_{y_n=+1} s_n$ in the step function. It represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has the posterior probability of being the positive class 1.
- If field `Type` is `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always 1.

Examples

Estimate Posterior Probabilities for New Data When Classes Are Inseparable

Load the `ionosphere` data set. Reserve 20 random observations of the data, and consider this set new data.

```
load ionosphere
n = size(X,1);
rng(1); % For reproducibility

indx = ~ismember([1:n],randsample(n,20)); % Indices for the training data
```

The classes of this data set are inseparable.

Train an SVM classifier using the training data. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X(indx,:),Y(indx),'ClassNames',{'b','g'},...
    'Standardize',true);
```

SVMModel is a ClassificationSVM classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as **g**. For efficiency, make a compact version of the SVM classifier SVMModel, and pass it and the new data to fitPosterior.

```
CompactSVMModel = compact(SVMModel);
[ScoreCSVMModel,ScoreParameters] = fitPosterior(CompactSVMModel,...
    X(~indx,:),Y(~indx));
```

```
ScoreTransform = ScoreCSVMModel.ScoreTransform
ScoreParameters
```

```
ScoreTransform =
```

```
'@(S)sigmoid(S,-1.098922e+00,4.519963e-01)'
```

```
ScoreParameters =
```

```
struct with fields:
```

```
    Type: 'sigmoid'
    Slope: -1.0989
    Intercept: 0.4520
```

ScoreTransform is the optimal score transform function. ScoreParameters is a structure array having three fields: the score transformation function name (Type), the sigmoid slope (Slope) and sigmoid intercept (Intercept) estimates.

Alternatively, you can pass SVMModel and the new data to fitSVMPosterior, but this does not have the benefit of efficiency.

Estimate the posterior probabilities that the observations in the new data are in class **g**.

```
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));
table(Y(~indx),labels,postProbs(:,2),...
      'VariableNames',{ 'TrueLabel', 'PredictedLabel', 'PosteriorProbability'})
```

```
ans =
```

```
20×3 table
```

TrueLabel	PredictedLabel	PosteriorProbability
'g'	'g'	0.78437
'b'	'b'	0.024588
'g'	'g'	0.82399
'b'	'b'	0.0061637
'b'	'b'	3.6118e-06
'b'	'b'	0.15688
'b'	'g'	0.9622
'b'	'b'	6.1348e-09
'b'	'b'	0.0019646
'g'	'g'	0.7251
'g'	'g'	0.70263
'b'	'b'	0.075298
'g'	'g'	0.90691
'g'	'g'	0.82849
'b'	'b'	0.051193
'g'	'g'	0.95331
'b'	'b'	0.0031877
'b'	'b'	0.16015
'g'	'g'	0.92008
'g'	'g'	0.91349

Estimate Posterior Probabilities for New Data When Classes Are Separable

Load Fisher's iris data set. Use the petal lengths and widths, and remove the virginica species from the data. Reserve 10 random observations of the data, and consider this set new data.

```
load fisheriris
classKeep = ~strcmp(species,'virginica');
X = meas(classKeep,3:4);
Y = species(classKeep);
```

```
rng(1); % For reproducibility
indx1 = 1:numel(species);
indx2 = indx1(classKeep);
indx = ~ismember(indx2,randsample(indx2,10)); % Indices for the training data

gscatter(X(indx,1),X(indx,2),Y(indx));
title('Scatter Diagram of Iris Measurements')
xlabel('Petal length')
ylabel('Petal width')
legend('Setosa','Versicolor')
```

The classes are perfectly separable. Therefore, the score-to-posterior-probability transformation function is a step function.

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X(indx,:),Y(indx),...  
    'ClassNames',{'setosa','versicolor'}, 'Standardize',true);
```

SVMModel is a ClassificationSVM classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as `versicolor`. For efficiency, make a compact version of the SVM classifier SVMModel, and pass it and the new data to `fitPosterior`.

```
CompactSVMModel = compact(SVMModel);  
[ScoreCSVMModel,ScoreParameters] = fitPosterior(CompactSVMModel,...  
    X(~indx,:),Y(~indx));
```

```
ScoreTransform = ScoreCSVMModel.ScoreTransform
```

```
Warning: Classes are perfectly separated. The optimal score-to-posterior  
transformation is a step function.
```

```
ScoreTransform =
```

```
'@(S)step(S,-1.338450e+00,2.012495e+00,5.333333e-01)'
```

`fitPosterior` displays a warning whenever the classes are separable, and stores the step function in `ScoreSVMModel.ScoreTransform`.

Display the score function type and its estimated values.

```
ScoreParameters
```

```
ScoreParameters =
```

```
struct with fields:
```

```
                Type: 'step'  
        LowerBound: -1.3385  
        UpperBound: 2.0125  
PositiveClassProbability: 0.5333
```

`ScoreParameters` is a structure array having four fields:

- The score transformation function type (`Type`)
- The score corresponding to negative class boundary (`LowerBound`)
- The score corresponding to positive class boundary (`UpperBound`)
- The positive class probability (`PositiveClassProbability`)

Alternatively, you can pass `SVMModel` and the new data to `fitSVMPosterior`, but this does not have the benefit of efficiency.

Estimate the posterior probabilities that the observations in the new data are versicolor irises.

```
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));
table(Y(~indx),labels,postProbs(:,2),...
      'VariableNames',{ 'TrueLabel', 'PredictedLabel', 'PosteriorProbability' })
```

ans =

10×3 table

TrueLabel	PredictedLabel	PosteriorProbability
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'versicolor'	'versicolor'	1
'versicolor'	'versicolor'	1

Since the classes are separable, the step function transforms the positive-class score to:

- 0, if the score is less than `ScoreParameters.LowerBound`
- 1, if the score is greater than `ScoreParameters.UpperBound`

- `ScoreParameters.PositiveClassProbability`, if the score is in the interval [`ScoreParameters.LowerBound` , `ScoreParameters.LowerBound`]

Definitions

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the output argument `ScoreTransform.Type` is `sigmoid`, then parameters A and B correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- s_j the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the output argument `ScoreTransform.Type` is `step`, then the quantities $\max_{y_k=-1} s_k$ and $\min_{y_k=+1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Tips

Here is one way to predict positive class posterior probabilities.

- 1 Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.
- 2 Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, for example, `ScoreSVMModel`, is the same, trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- 3 Pass the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) and predictor data matrix to `predict`. The second column of the second output argument stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

Algorithms

If you reestimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to `'none'` before estimating the new one

Alternatives

You can also estimate the optimal score-to-posterior-probability function using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad since it accepts a wider range of SVM classifier types.

fitrensemble

Fit ensemble of learners for regression

Syntax

```
Mdl = fitrensemble(Tbl,ResponseVarName)
```

```
Mdl = fitrensemble(Tbl,formula)
```

```
Mdl = fitrensemble(Tbl,Y)
```

```
Mdl = fitrensemble(X,Y)
```

```
Mdl = fitrensemble( ____,Name,Value)
```

Description

`Mdl = fitrensemble(Tbl,ResponseVarName)` returns the trained regression ensemble model object (`Mdl`) that contains the results of boosting 100 regression trees using LSBoost and the predictor and response data in the table `Tbl`. `ResponseVarName` is the name of the response variable in `Tbl`.

`Mdl = fitrensemble(Tbl,formula)` applies `formula` to fit the model to the predictor and response data in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`. For example, `'Y~X1+X2+X3'` fits the response variable `Tbl.Y` as a function of the predictor variables `Tbl.X1`, `Tbl.X2`, and `Tbl.X3`.

`Mdl = fitrensemble(Tbl,Y)` treats all variables in the table `Tbl` as predictor variables. `Y` is the vector of responses that is not in `Tbl`.

`Mdl = fitrensemble(X,Y)` uses the predictor data in the matrix `X` and response data in the vector `Y`.

`Mdl = fitrensemble(____,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments and any of the input arguments in the previous syntaxes. For example, you can specify the number of learning cycles, the ensemble-aggregation method, or to implement 10-fold cross-validation.

Examples

Train Regression Ensemble

Create a regression ensemble that predicts the fuel economy of a car given the number of cylinders, volume displaced by the cylinders, horsepower, and weight. Then, train another ensemble using fewer predictors. Compare the in-sample predictive accuracies of the ensembles.

Load the `carsmall` data set. Store the variables to be used in training in a table.

```
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

Train a regression ensemble.

```
Mdl1 = fitensemble(Tbl,'MPG');
```

`Mdl1` is a `RegressionEnsemble` model. Some notable characteristics of `Mdl1` are:

- The ensemble-aggregation algorithm is 'LSBoost'.
- Because the ensemble-aggregation method is a boosting algorithm, regression trees that allow a maximum of 10 splits compose the ensemble.
- One hundred trees compose the ensemble.

Because `MPG` is a variable in the MATLAB® Workspace, you can obtain the same result by entering

```
Mdl1 = fitensemble(Tbl,MPG);
```

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

```
pMPG = predict(Mdl1,[4 200 150 3000])
```

```
pMPG =
```

```
25.6467
```

Train a new ensemble using all predictors in `Tbl` except `Displacement`.

```
formula = 'MPG ~ Cylinders + Horsepower + Weight';
Mdl2 = fitensemble(Tbl,formula);
```

Compare the resubstitution MSEs between Mdl1 and Mdl2.

```
mse1 = resubLoss(Mdl1)
mse2 = resubLoss(Mdl2)
```

```
mse1 =
    0.3096
```

```
mse2 =
    0.5861
```

The in-sample MSE for the ensemble that trains on all predictors is lower.

Estimate Generalization Error of Boosting Ensemble

Estimate the generalization error of an ensemble of boosted regression trees.

Load the `carsmall` data set. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors of fuel economy.

```
load carsmall
X = [Cylinders Displacement Horsepower Weight];
```

Cross-validate an ensemble of regression trees using 10-fold cross-validation. Using a decision tree template, specify that each tree should be a split once only.

```
rng(1); % For reproducibility
t = templateTree('MaxNumSplits',1);
Mdl = fitrensemble(X,MPG,'Learners',t,'CrossVal','on');
```

Mdl is a `RegressionPartitionedEnsemble` model.

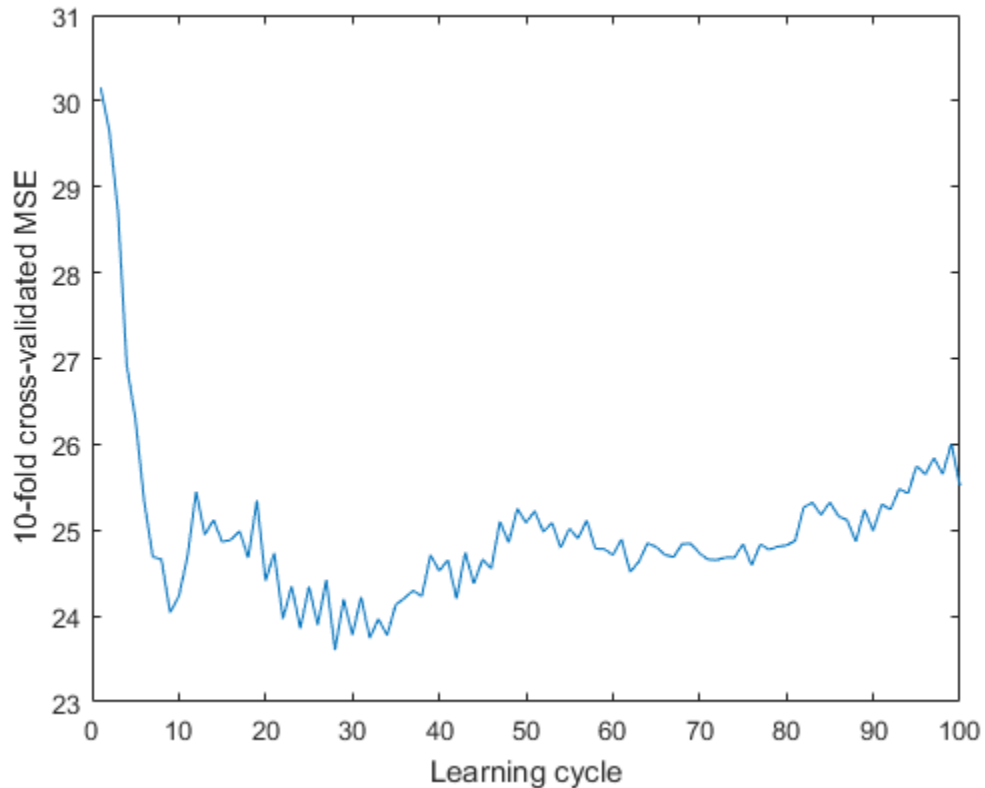

Plot the cumulative, 10-fold cross-validated, mean-squared error (MSE). Display the estimated generalization error of the ensemble.

```
kflc = kfoldLoss(Mdl,'Mode','cumulative');
figure;
plot(kflc);
ylabel('10-fold cross-validated MSE');
xlabel('Learning cycle');
```

```
estGenError = kflc(end)
```

```
estGenError =
```

```
25.5184
```

`kfoldLoss` returns the generalization error by default. However, plotting the cumulative loss allows you to monitor how the loss changes as weak learners accumulate in the ensemble.

The ensemble achieves an MSE of around 23.5 after accumulating about 30 weak learners.

If you are satisfied with the generalization error of the ensemble, then, to create a predictive model, train the ensemble again using all of the settings except cross-validation. However, it is good practice to tune hyperparameters such as the maximum number of decision splits per tree and the number of learning cycles..

Optimize Regression Ensemble

This example shows how to optimize hyperparameters automatically using `fitrensemble`. The example uses the `carsmall` data.

Load the data.

```
load carsmall
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
rng(1)
Mdl = fitrensemble([Horsepower,Weight],MPG,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
    'expected-improvement-plus'))
```

Optimization completed.

MaxObjectiveEvaluations of 30 reached.

Total function evaluations: 30

Total elapsed time: 399.6457 seconds.

Total objective function evaluation time: 289.4511

Best observed feasible point:

Method	NumLearningCycles	LearnRate	MinLeafSize
Bag	57	NaN	10

Observed objective function value = 2.7671

Estimated objective function value = 2.7802

Function evaluation time = 1.9671

Best estimated feasible point (according to models):

Method	NumLearningCycles	LearnRate	MinLeafSize
Bag	494	NaN	9

Estimated objective function value = 2.7802

Estimated function evaluation time = 17.5242

```
Mdl =  
  
classreg.learning.regr.RegressionBaggedEnsemble  
    ResponseName: 'Y'  
    CategoricalPredictors: []  
    ResponseTransform: 'none'  
    NumObservations: 94  
    HyperparameterOptimizationResults: [1x1 BayesianOptimization]  
    NumTrained: 494  
    Method: 'Bag'  
    LearnerNames: {'Tree'}  
    ReasonForTermination: 'Terminated normally after completing the request'  
    FitInfo: []  
    FitInfoDescription: 'None'  
    Regularization: []  
    FResample: 1  
    Replace: 1  
    UseObsForLearner: [94x494 logical]
```

The optimization searched over the methods for regression (`Bag` and `LSBoost`), over `NumLearningCycles`, over the `LearnRate` for `LSBoost`, and over the tree learner `MinLeafSize`. The output is the ensemble regression with the minimum estimated cross-validation loss.

Create Predictive Ensemble Using Cross-Validation

One way to create an ensemble of boosted regression trees that has satisfactory predictive performance is to tune the decision tree-complexity level using cross-validation. While searching for an optimal complexity level, tune the learning rate to minimize the number of learning cycles.

Load the `carsmall` data set. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors of fuel economy.

```
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

To search for the optimal tree-complexity level:

- 1 Cross-validate a set of ensembles. Exponentially increase the tree-complexity level for subsequent ensembles from decision stump (one split) to at most $n - 1$ splits. n is the sample size. Also, vary the learning rate for each ensemble between 0.1 to 1.
- 2 Estimate the cross-validated mean-squared error (MSE) for each ensemble.
- 3 For tree-complexity level $j, j = 1 \dots J$, compare the cumulative, cross-validated MSE of the ensembles by plotting them against number of learning cycles. Plot separate curves for each learning rate on the same figure.
- 4 Choose the curve that achieves the minimal MSE, and note the corresponding learning cycle and learning rate.

Cross-validate a deep regression tree and a stump. Because the data contain missing values, use surrogate splits. These regression trees serve as benchmarks.

```
rng(1); % For reproducibility
MdlDeep = fitrtree(Tbl,'MPG','CrossVal','on','MergeLeaves','off',...
    'MinParentSize',1,'Surrogate','on');
MdlStump = fitrtree(Tbl,'MPG','MaxNumSplits',1,'CrossVal','on',...
    'Surrogate','on');
```

Cross-validate an ensemble of 150 boosted regression trees using 5-fold cross-validation. Using a tree template:

- Vary the maximum number of splits using the values in the sequence $\{2^0, 2^1, \dots, 2^m\}$. m is such that 2^m is no greater than $n - 1$.
- Turn on surrogate splits.

For each variant, adjust the learning rate using each value in the set $\{0.1, 0.25, 0.5, 1\}$;

```
n = size(Tbl,1);
m = floor(log2(n - 1));
learnRate = [0.1 0.25 0.5 1];
numLR = numel(learnRate);
```

```

maxNumSplits = 2.^(0:m);
numMNS = numel(maxNumSplits);
numTrees = 150;
Mdl = cell(numMNS,numLR);

for k = 1:numLR;
    for j = 1:numMNS;
        t = templateTree('MaxNumSplits',maxNumSplits(j),'Surrogate','on');
        Mdl{j,k} = fitrensemble(Tbl,'MPG','NumLearningCycles',numTrees,...
            'Learners',t,'KFold',5,'LearnRate',learnRate(k));
    end;
end;

```

Estimate the cumulative, cross-validated MSE of each ensemble.

```

kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(learnRate)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);

```

Plot how the cross-validated MSE behaves as the number of trees in the ensemble increases. Plot the curves with respect to learning rate on the same plot, and plot separate plots for varying tree-complexity levels. Choose a subset of tree complexity levels to plot.

```

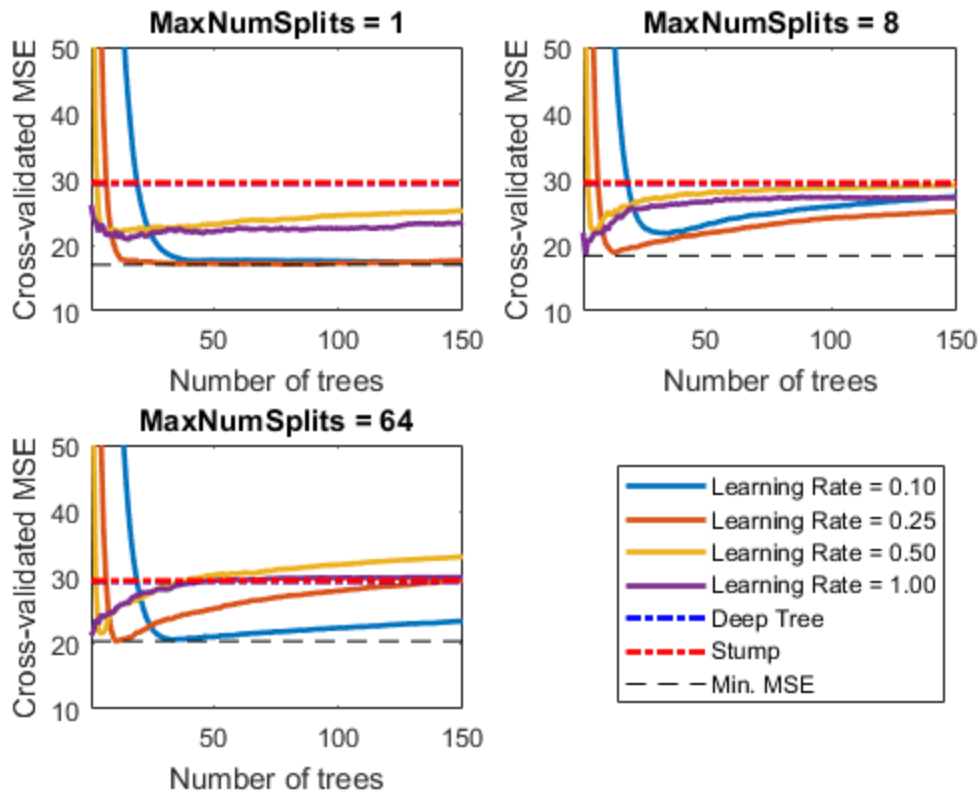

mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3;
    subplot(2,2,k);
    plot(squeeze(error(:,mnsPlot(k),:)),'LineWidth',2);
    axis tight;
    hold on;
    h = gca;
    plot(h.XLim,[errorDeep errorDeep],'-b','LineWidth',2);
    plot(h.XLim,[errorStump errorStump],'-r','LineWidth',2);
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1], '--k');
    h.YLim = [10 50];
    xlabel 'Number of trees';
    ylabel 'Cross-validated MSE';
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))));
    hold off;
end;
hL = legend([cellstr(num2str(learnRate),'Learning Rate = %0.2f'));...

```

```

    'Deep Tree'; 'Stump'; 'Min. MSE']]);
    hL.Position(1) = 0.6;

```

Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.

```

[minErr,minErrIdxLin] = min(error(:));
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);

fprintf('\nMin. MSE = %0.5f',minErr)

```

```
fprintf('\nOptimal Parameter Values:\nNum. Trees = %d',idxNumTrees);
fprintf('\nMaxNumSplits = %d\nLearning Rate = %0.2f\n',...
        maxNumSplits(idxMNS),learnRate(idxLR))
```

```
Min. MSE = 17.01148
Optimal Parameter Values:
Num. Trees = 38
MaxNumSplits = 4
Learning Rate = 0.10
```

Create a predictive ensemble based on the optimal hyperparameters and the entire training set.

```
tFinal = templateTree('MaxNumSplits',maxNumSplits(idxMNS),'Surrogate','on');
MdlFinal = fitrensemble(Tbl,'MPG','NumLearningCycles',idxNumTrees,...
    'Learners',tFinal,'LearnRate',learnRate(idxLR))
```

```
MdlFinal =
```

```
classreg.learning.regr.RegressionEnsemble
    PredictorNames: {1×4 cell}
    ResponseName: 'MPG'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    NumObservations: 94
    NumTrained: 38
    Method: 'LSBoost'
    LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number o
    FitInfo: [38×1 double]
    FitInfoDescription: {2×1 cell}
    Regularization: []
```

`MdlFinal` is a `RegressionEnsemble`. To predict the fuel economy of a car given its number of cylinders, volume displaced by the cylinders, horsepower, and weight, pass the predictor data and `MdlFinal` to `predict`.

- “Supervised Learning Workflow and Algorithms” on page 18-2
- “Ensemble Methods” on page 18-71

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of **Tbl** corresponds to one observation, and each column corresponds to one predictor variable. **Tbl** can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If **Tbl** contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using **ResponseVarName**.
- If **Tbl** contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using **formula**.
- If **Tbl** does not contain the response variable, then specify the response data using **Y**. The length of response variable and the number of rows of **Tbl** must be equal.

Note: To save memory and execution time, supply **X** and **Y** instead of **Tbl**.

Data Types: table

ResponseVarName — Response variable name

name of response variable in **Tbl**

Response variable name, specified as the name of the response variable in **Tbl**.

You must specify **ResponseVarName** as a character vector. For example, if **Tbl.Y** is the response variable, then specify **ResponseVarName** as 'Y'. Otherwise, **fitrensemble** treats all columns of **Tbl** as predictor variables.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

For classification, you can specify the order of the classes using the **ClassNames** name-value pair argument. Otherwise, **fitrensemble** determines the class order, and stores it in the **Mdl.ClassNames**.

Data Types: char

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of 'Y~X1+X2+X3'. In this form, Y represents the response variable, and X1, X2, and X3 represent the predictor variables. The variables must be variable names in Tbl (Tbl.Properties.VariableNames).

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

Data Types: char

X — Predictor data

numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of Y and the number of rows of X must be equal.

To specify the names of the predictors in the order of their appearance in X, use the PredictorNames name-value pair argument.

Data Types: double | single

Y — Response

numeric vector

Response, specified as a numeric vector. Each element in Y is the response to the observation in the corresponding row of X or Tbl. The length of Y and the number of rows of X or Tbl must be equal.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Note: You cannot use any cross-validation name-value pair along with `OptimizeHyperparameters`. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair.

Example: `'NumLearningCycles',500,'Learners','KNN','CrossVal','on'` specifies to cross-validate an ensemble of 500 bagged regression trees using 10-fold cross-validation.

General Ensemble Options

'Method' — Ensemble-aggregation method

'LSBoost' (default) | 'Bag'

Ensemble-aggregation method, specified as the comma separated pair consisting of 'Method' and 'Bag' or 'LSBoost'.

Value	Description
'Bag'	Bootstrap aggregating or bagging (for example, random forest)
'LSBoost'	Least-squares boosting or LSBoost

Example: `'Method','Bag'`

Data Types: char

'NumLearningCycles' — Number of ensemble learning cycles

100 (default) | positive integer

Number of ensemble learning cycles, specified as a positive integer. At every learning cycle, the software trains one weak learner for every template object in `Learners`. Consequently, the software trains `NumLearningCycles*numel(Learners)` learners.

The software composes the ensemble using all trained learners and stores them in `Mdl.Trained`.

For more details, see “Tips” on page 29-2546.

Example: `'NumLearningCycles',500`

Data Types: `single` | `double`

'Learners' — Weak learners to use in ensemble

'tree' (default) | regression tree template object | cell vector of regression tree template objects

Weak learners to use in the ensemble, specified as 'tree', regression tree template object, or cell array of regression tree template objects.

- 'tree' specifies to train an ensemble of regression trees using default regression tree options.
 - For bagging, `fitensemble` grows deep trees by default. For a complete list of defaults, see `templateTree`.
 - For LSBoost, `fitensemble` grows shallow trees by default. That is, `Learners` is `templateTree('MaxNumSplits',10)`.
- A regression tree template object specifies how to grow all trees in the ensemble. You can create a regression tree template using `templateTree`.
- A cell vector of m regression tree templates specifies to grow m regression trees per learning cycle (see `NumLearningCycles`). For example, for an ensemble composed of two types of regression trees, supply `{t1 t2}`, where `t1` and `t2` are regression tree templates returned by `templateTree`.

If you specify 'Learners', `learners` explicitly, where `learners` is a weak-learner name or template object, then `fitensemble` defers to the corresponding template object to choose any required default values for weak-learner name-value pair arguments. For example, if you specify 'Learners', 'tree' and a boosting algorithm, then the tree template object overrides the default maximum number of splits of ten, and grows decision stumps (one allowable split) instead.

For details on the number of learners to train, see `NumLearningCycles` and “Tips” on page 29-2546.

'NPrint' — Printout frequency

'off' (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of 'NPrint' and a positive integer or 'off'.

To track the number of *weak learners* or *folds* that `fitensemble` trained so far, specify a positive integer. That is, if you specify the positive integer m :

- Without also specifying any cross-validation option (for example, `CrossVal`), then `fitrensemble` displays a message to the command line every time it completes training m weak learners.
- And a cross-validation option, then `fitrensemble` displays a message to the command line every time it finishes training m folds.

If you specify `'off'`, then `fitrensemble` does not display a message when it completes training weak learners.

Tip: When training an ensemble of many weak learners on a large data set, specify a positive integer for `NPrint`.

Example: `'NPrint',5`

Data Types: `single` | `double` | `char`

'CategoricalPredictors' — Categorical predictors list

character matrix | logical vector | numeric vector | cell array of character vectors | `'all'`

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following:

- A numeric vector with indices from 1 through p , where p is the number of columns of X .
- A logical vector of length p , where a `true` entry means that the corresponding column of X is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
- `'all'`, meaning all predictors are categorical.

By default, if the predictor data is in a matrix (X), `fitrensemble` assumes that none of the predictors are categorical. If the predictor data is in a table (`Tbl`), `fitrensemble` assumes that a variable is categorical if it contains logical values, categorical values, or a cell array of character vectors.

Example: `'CategoricalPredictors', 'all'`

Data Types: `single` | `double` | `char`

'PredictorNames' — Predictor variable names

cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `'PredictorNames'` to give the predictor variables in `X` names.
 - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
 - By default, `PredictorNames` is `{x1,x2,...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitrensemble` uses the predictor variables in `PredictorNames` and the response only in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It good practice to specify the predictors for training using one of `'PredictorNames'` or `formula` only.

Example: `'PredictorNames', {'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth'}`

Data Types: `cell`

'ResponseName' — Response variable name

`'Y'` (default) | character vector

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.

- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName', 'response'`

Data Types: char

Cross-Validation Options

'CrossVal' — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval` or `crossval`.

Example: `'Crossval', 'on'`

Data Types: char

'CVPartition' — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', ρ` , then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify, e.g., `'KFold', k`, then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold', 5`

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout', 'on'`, then, for each of the n observations, where n is `size(Mdl.X, 1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout', 'on'`

Data Types: `char`

Other Regression Options

'Weights' — Observation weights

numeric vector of positive values | character vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n, 1)`, where n is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char`

Sampling Options

'FResample' — Fraction of training set to resample

1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of `'FResample'` and a positive scalar in (0,1].

To use `'FResample'`, specify `'bag'` for `Method` or set `Resample` to `'on'`.

Example: `'FResample', 0.75`

Data Types: `single` | `double`

'Replace' — Flag indicating to sample with replacement

'on' (default) | 'off'

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of 'Replace' and 'off' or 'on'.

- For 'on', the software samples the training observations with replacement.
- For 'off', the software samples the training observations without replacement. If you set `Resample` to 'on', then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set `Method` to 'bag' or set `Resample` to 'on', `Replace` has no effect.

Example: 'Replace', 'off'

Data Types: char

'Resample' — Flag indicating to resample

'off' | 'on'

Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If `Method` is any boosting method, then:
 - 'Resample', 'on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
 - 'Resample', 'off' specifies to reweight observations at every learning iteration. This setting is the default.
- If `Method` is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see `FResample`) with or without replacement (see `Replace`).

LSBoost Method Options

'LearnRate' — Learning rate for shrinkage

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: `'LearnRate', 0.1`

Data Types: `single` | `double`

Hyperparameter Optimization

'OptimizeHyperparameters' — Parameters to optimize

'none' (default) | 'auto' | 'all' | cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as:

- 'none' — Do not optimize.
- 'auto' — Use {'Method', 'NumLearningCycles', 'LearnRate'} along with the default parameters for the specified `Learners`:
 - `Learners = 'tree'` (default) — {'MinLeafSize'}

Note: For hyperparameter optimization, `Learners` must be a single argument, not a cell array.

- 'all' — Optimize all eligible parameters.
- Cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitrensemble` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note: `OptimizeHyperparameters` values override any values you set using other name-value pairs. For example, setting `OptimizeHyperparameters` to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitrensemble` are:

- **Method** — Eligible methods are 'Bag' or 'RSBoost'.
- **NumLearningCycles** — `fitrensemble` searches among positive integers, by default log-scaled with range [10,500].
- **LearnRate** — `fitrensemble` searches among positive reals, by default log-scaled with range [1e-3,1].
- **MinLeafSize** — `fitrensemble` searches among integers log-scaled in the range [1,max(2,floor(NumObservations/2))].
- **MaxNumSplits** — `fitrensemble` searches among integers log-scaled in the range [1,max(2,NumObservations-1)].
- **NumVariablesToSample** — `fitrensemble` searches among integers in the range [1,max(2,NumPredictors)].

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load carsmall
params = hyperparameters('fitrensemble',[Horsepower,Weight],MPG,'Tree');
params(4).Range = [1,20];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression, and the misclassification rate for classification. To control the iterative display, set the `HyperparameterOptimizationOptions` name-value pair, `Verbose` field. To control the plots, set the `HyperparameterOptimizationOptions` name-value pair, `ShowPlots` field.

For an example, see “Optimize Regression Ensemble” on page 29-2523.

Example: 'auto'

Data Types: char | cell

'HyperparameterOptimizationOptions' — Options for optimization structure

Options for optimization, specified as a structure. Modifies the effect of the `OptimizeHyperparameters` name-value pair. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the <code>commandsortrows(Mdl.ParameterOptim.</code></p>	'bayesopt'
AcquisitionFunc	<ul style="list-style-type: none"> 'expected-improvement-per-second-plus' 'expected-improvement' 'expected-improvement-plus' 'expected-improvement-per-second' 'lower-confidence-bound' 'probability-of-improvement' <p>For details, see the <code>bayesopt</code> <code>AcquisitionFunctionName</code> name-value pair, or “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEva	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'

Field Name	Values	Default
NumGridDivision	For 'gridsearch', the number of values in each dimension. Can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. Ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , plots the best objective function value against iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is 'bayesopt', then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediate	Logical value indicating whether to save results when <code>Optimizer</code> is 'bayesopt'. If <code>true</code> , overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesoptVerbose</code> name-value pair.	1

Field Name	Values	Default
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If false , the optimizer uses a single partition for the optimization. true usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, true requires at least twice as many function evaluations.	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code>	Kfold = 5
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example: `struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

Mdl1 — Trained regression ensemble model

RegressionBaggedEnsemble model object | RegressionEnsemble model object | RegressionPartitionedEnsemble cross-validated model object

Trained ensemble model, returned as one of the model objects in this table.

Model Object	Specify Any Cross-Validation Options?	Method Setting	Resample Setting
RegressionBaggedEnsemble	No	'Bag'	'on'
RegressionEnsemble	No	'LSBoost'	'off'
RegressionPartitionedEnsemble	Yes	'LSBoost' or 'Bag'	'off' or 'on'

The name-value pair arguments that control cross-validation are `CrossVal`, `Holdout`, `KFold`, `Leaveout`, and `CVPartition`.

To reference properties of `Mdl`, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

Tips

- `NumLearningCycles` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume`.
- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.
- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.

Algorithms

- For details of ensemble-aggregation algorithms, see “Ensemble Algorithms” on page 18-169.
- If you specify `'Method'`, `'LSBoost'`, then the software grows shallow decision trees by default. You can adjust tree depth by specifying the `MaxNumSplits`, `MinLeafSize`, and `MinParentSize` name-value pair arguments using `templateTree`.
- For dual-core systems and above, `fitensemble` parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

fitrsvm

Fit a support vector machine regression model

`fitrsvm` trains or cross-validates a support vector machine (SVM) regression model on a low- through moderate-dimensional predictor data set. `fitrsvm` supports mapping the predictor data using kernel functions, and supports SMO, ISDA, or *L1* soft-margin minimization via quadratic programming for objective-function minimization.

To train a linear SVM regression model on a high-dimensional data set, that is, data sets that include many predictor variables, use `fitrlinear` instead.

To train an SVM model for binary classification, see `fitcsvm` for low- through moderate-dimensional predictor data sets, or `fitclinear` for high-dimensional data sets.

Syntax

```
Mdl = fitrsvm(Tbl,ResponseVarName)
```

```
Mdl = fitrsvm(Tbl,formula)
```

```
Mdl = fitrsvm(Tbl,Y)
```

```
Mdl = fitrsvm(X,Y)
```

```
Mdl = fitrsvm( ____,Name,Value)
```

Description

`Mdl = fitrsvm(Tbl,ResponseVarName)` returns a full, trained support vector machine (SVM) regression model `Mdl` trained using the predictors values in the table `Tbl` and the response values in `Tbl.ResponseVarName`.

`Mdl = fitrsvm(Tbl,formula)` returns a full SVM regression model trained using the predictors values in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitrsvm(Tbl,Y)` returns a full, trained SVM regression model trained using the predictors values in the table `Tbl` and the response values in the vector `Y`.

`Mdl = fitrsvm(X,Y)` returns a full, trained SVM regression model trained using the predictors values in the matrix `X` and the response values in the vector `Y`.

`Mdl = fitrsvm(____,Name,Value)` returns an SVM regression model with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the kernel function or train a cross-validated model.

Examples

Train Linear Support Vector Machine Regression Model

Train a support vector machine (SVM) regression model using sample data stored in matrices.

Load the `carsmall` data set.

```
load carsmall
rng 'default' % For reproducibility
```

Specify `Horsepower` and `Weight` as the predictor variables (`X`) and `MPG` as the response variable (`Y`).

```
X = [Horsepower,Weight];
Y = MPG;
```

Train a default SVM regression model.

```
Mdl = fitrsvm(X,Y)
```

```
Mdl =
```

```
RegressionSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'
                Alpha: [76×1 double]
                Bias: 43.1920
    KernelParameters: [1×1 struct]
    NumObservations: 93
```

```
BoxConstraints: [93×1 double]
ConvergenceInfo: [1×1 struct]
IsSupportVector: [93×1 logical]
Solver: 'SMO'
```

Mdl is a trained `RegressionSVM` model.

Check the model for convergence.

```
Mdl.ConvergenceInfo.Converged
```

```
ans =
    logical
     0
```

0 indicates that the model did not converge.

Retrain the model using standardized data.

```
MdlStd = fitrsvm(X,Y,'Standardize',true)
```

```
MdlStd =
    RegressionSVM
        ResponseName: 'Y'
    CategoricalPredictors: []
        ResponseTransform: 'none'
            Alpha: [77×1 double]
            Bias: 22.9131
    KernelParameters: [1×1 struct]
            Mu: [109.3441 2.9625e+03]
            Sigma: [45.3545 805.9668]
    NumObservations: 93
        BoxConstraints: [93×1 double]
    ConvergenceInfo: [1×1 struct]
    IsSupportVector: [93×1 logical]
    Solver: 'SMO'
```

Check the model for convergence.

```
MdlStd.ConvergenceInfo.Converged
```

```
ans =
```

```
    logical
```

```
    1
```

1 indicates that the model did converge.

Compute the resubstitution (in-sample) mean-squared error for the new model.

```
lStd = resubLoss(MdlStd)
```

```
lStd =
```

```
    17.0256
```

Train Support Vector Machine Regression Model

Train a support vector machine regression model using the abalone data from the UCI Machine Learning Repository.

Download the data and save it in your current folder with the name 'abalone.csv'.

```
url = 'https://archive.ics.uci.edu/ml/machine-learning-databases/abalone/abalone.data';
websave('abalone.csv',url);
```

Read the data into a table. Specify the variable names.

```
varnames = {'Sex'; 'Length'; 'Diameter'; 'Height'; 'Whole_weight';...
            'Shucked_weight'; 'Viscera_weight'; 'Shell_weight'; 'Rings'};
Tbl = readtable('abalone.csv','Filetype','text','ReadVariableNames',false);
Tbl.Properties.VariableNames = varnames;
```

The sample data contains 4177 observations. All the predictor variables are continuous except for `Sex`, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings (stored in `Rings`) on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
rng default % For reproducibility
Mdl = fitsvm(Tbl,'Rings','KernelFunction','gaussian','KernelScale','auto',...
            'Standardize',true)
```

```
Mdl =
```

```
RegressionSVM
    PredictorNames: {1×8 cell}
    ResponseName: 'Rings'
    CategoricalPredictors: 1
    ResponseTransform: 'none'
        Alpha: [3635×1 double]
        Bias: 10.8144
    KernelParameters: [1×1 struct]
        Mu: [1×10 double]
        Sigma: [1×10 double]
    NumObservations: 4177
    BoxConstraints: [4177×1 double]
    ConvergenceInfo: [1×1 struct]
    IsSupportVector: [4177×1 logical]
    Solver: 'SMO'
```

The Command Window shows that `Mdl` is a trained `RegressionSVM` model and displays a property list.

Display the properties of `Mdl` using dot notation. For example, check to confirm whether the model converged and how many iterations it completed.

```
conv = Mdl.ConvergenceInfo.Converged
iter = Mdl.NumIterations
```

```
conv =
```

```

logical
    1

iter =
    2759

```

The returned results indicate that the model converged after 2759 iterations.

Cross-Validate SVM Regression Model

Load the `carsmall` data set.

```

load carsmall
rng 'default' % For reproducibility

```

Specify Horsepower and Weight as the predictor variables (X) and MPG as the response variable (Y).

```

X = [Horsepower Weight];
Y = MPG;

```

Cross-validate two SVM regression models using 5-fold cross-validation. For both models, specify to standardize the predictors. For one of the models, specify to train using the default linear kernel, and the Gaussian kernel for the other model.

```

MdlLin = fitrsvm(X,Y,'Standardize',true,'KFold',5)
MdlGau = fitrsvm(X,Y,'Standardize',true,'KFold',5,'KernelFunction','gaussian')
MdlLin.Trained

```

```

MdlLin =

classreg.learning.partition.RegistrationPartitionedSVM
  CrossValidatedModel: 'SVM'
  PredictorNames: {'x1' 'x2'}
  ResponseName: 'Y'
  NumObservations: 94
  KFold: 5
  Partition: [1×1 cvpartition]

```

```
ResponseTransform: 'none'
```

```
MdlGau =
```

```
classreg.learning.partition.RegressionPartitionedSVM  
  CrossValidatedModel: 'SVM'  
    PredictorNames: {'x1' 'x2'}  
      ResponseName: 'Y'  
    NumObservations: 94  
      KFold: 5  
    Partition: [1×1 cvpartition]  
  ResponseTransform: 'none'
```

```
ans =
```

```
5×1 cell array
```

```
[1×1 classreg.learning.regr.CompactRegressionSVM]  
[1×1 classreg.learning.regr.CompactRegressionSVM]  
[1×1 classreg.learning.regr.CompactRegressionSVM]  
[1×1 classreg.learning.regr.CompactRegressionSVM]  
[1×1 classreg.learning.regr.CompactRegressionSVM]
```

MdlLin and **MdlGau** are **RegressionPartitionedSVM** cross-validated models. The **Trained** property of each model is a 5-by-1 cell array of **CompactRegressionSVM** models. The models in the cell store the results of training on 4 folds of observations, and leaving one fold of observations out.

Compare the generalization error of the models. In this case, the generalization error is the out-of-sample mean-squared error.

```
mseLin = kfoldLoss(MdlLin)  
mseGau = kfoldLoss(MdlGau)
```

```
mseLin =
```

```
17.4417
```

```
mseGau =  
    16.7333
```

The SVM regression model using the Gaussian kernel performs better than the one using the linear kernel.

Create a model suitable for making predictions by passing the entire data set to `ftrsvm`, and specify all name-value pair arguments that yielded the better-performing model. However, do not specify any cross-validation options.

```
MdlGau = ftrsvm(X,Y, 'Standardize', true, 'KernelFunction', 'gaussian');
```

To predict the MPG of a set of cars, pass `Mdl` and a table containing the horsepower and weight measurements of the cars to `predict`.

Optimize SVM Regression

This example shows how to optimize hyperparameters automatically using `ftrsvm`. The example uses the `carsmall` data.

Load the `carsmall` data set.

```
load carsmall
```

Specify `Horsepower` and `Weight` as the predictor variables (X) and `MPG` as the response variable (Y).

```
X = [Horsepower Weight];  
Y = MPG;
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
rng default  
Mdl = ftrsvm(X,Y, 'OptimizeHyperparameters', 'auto', ...  
    'HyperparameterOptimizationOptions', struct('AcquisitionFunctionName', ...
```

'expected-improvement-plus'))

30	Accept	2.9185	0.11999	2.8849	2.9046	262.95

Optimization completed.
 MaxObjectiveEvaluations of 30 reached.
 Total function evaluations: 30

Total elapsed time: 177.8757 seconds.
 Total objective function evaluation time: 76.9088

Best observed feasible point:

BoxConstraint	KernelScale	Epsilon
761.43	988.48	2.9861

Observed objective function value = 2.8849
 Estimated objective function value = 2.9046
 Function evaluation time = 0.17016

Best estimated feasible point (according to models):

BoxConstraint	KernelScale	Epsilon
262.95	913.07	1.9138

Estimated objective function value = 2.9046
 Estimated function evaluation time = 0.12074

        Solver: 'SMO'
  
```

The optimization searched over `BoxConstraint`, `KernelScale`, and `Epsilon`. The output is the regression with the minimum estimated cross-validation loss.

Input Arguments

Tb1 — Predictor data

table

Sample data used to train the model, specified as a table. Each row of `Tb1` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tb1` can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

If a row of `Tbl` or an element of `Y` contains at least one `NaN`, then `fitrsvm` removes those rows and elements from both arguments when training the model.

To specify the names of the predictors in the order of their appearance in `Tbl`, use the `PredictorNames` name-value pair argument.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector. For example, if `Tbl` stores the response variable `Y` as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char`

Y — Response data

numeric vector

Response data, specified as an n -by-1 numeric vector. The length of Y and the number of rows of $Tb1$ or X must be equal.

If a row of $Tb1$ or X , or an element of Y , contains at least one NaN, then `fitrsvm` removes those rows and elements from both arguments when training the model.

To specify the response variable name, use the `ResponseName` name-value pair argument.

Data Types: `single` | `double`

X — Predictor data

numeric matrix

Predictor data to which the SVM regression model is fit, specified as an n -by- p numeric matrix. n is the number of observations and p is the number of predictor variables.

The length of Y and the number of rows of X must be equal.

If a row of X or an element of Y contains at least one NaN, then `fitrsvm` removes those rows and elements from both arguments.

To specify the names of the predictors in the order of their appearance in X , use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note: You cannot use any cross-validation name-value pair along with `OptimizeHyperparameters`. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair.

Example:

`'KernelFunction', 'gaussian', 'Standardize', true, 'CrossVal', 'on'` trains a

10-fold cross-validated SVM regression model using a Gaussian kernel and standardized training data.

Support Vector Machine Options

'BoxConstraint' — Box constraint

positive scalar value

Box constraint for the alpha coefficients, specified as the comma-separated pair consisting of 'BoxConstraint' and a positive scalar value.

The absolute value of the Alpha coefficients cannot exceed the value of **BoxConstraint**.

The default **BoxConstraint** value for the 'gaussian' or 'rbf' kernel function is $\text{iqr}(Y)/1.349$, where $\text{iqr}(Y)$ is the interquartile range of response variable Y . For all other kernels, the default **BoxConstraint** value is 1.

Example: **BoxConstraint**, 10

Data Types: single | double

'KernelFunction' — Kernel function

'linear' (default) | 'gaussian' | 'rbf' | 'polynomial' | function name

Kernel function used to compute the Gram matrix, specified as the comma-separated pair consisting of 'KernelFunction' and a value in this table.

Value	Description	Formula
'gaussian' or 'rbf'	Gaussian or Radial Basis Function (RBF) kernel	$G(x_1, x_2) = \exp\left(-\ x_1 - x_2\ ^2\right)$
'linear'	Linear kernel	$G(x_1, x_2) = x_1'x_2$
'polynomial'	Polynomial kernel. Use 'PolynomialOrder', p to specify a polynomial kernel of order p .	$G(x_1, x_2) = (1 + x_1'x_2)^p$

You can set your own kernel function, for example, **kernel**, by setting 'KernelFunction', 'kernel'. **kernel** must have the following form:

```
function G = kernel(U,V)
```

where:

- U is an m -by- p matrix.
- V is an n -by- p matrix.
- G is an m -by- n Gram matrix of the rows of U and V .

And `kernel.m` must be on the MATLAB path.

It is good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function `'mysigmoid'` rather than `'sigmoid'`.

Example: `'KernelFunction', 'gaussian'`

Data Types: char

'KernelScale' — Kernel scale parameter

1 (default) | `'auto'` | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of `'KernelScale'` and `'auto'` or a positive scalar. The software divides all elements of the predictor matrix X by the value of `KernelScale`. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

- If you specify `'auto'`, then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed using `rng` before training.
- If you specify `KernelScale` and your own kernel function, for example, `kernel`, using `'KernelFunction', 'kernel'`, then the software throws an error. You must apply scaling within `kernel`.

Example: `'KernelScale', 'auto'`

Data Types: double | single | char

'PolynomialOrder' — Polynomial kernel function order

3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of `'PolynomialOrder'` and a positive integer.

If you set `'PolynomialOrder'` and `KernelFunction` is not `'polynomial'`, then the software throws an error.

Example: 'PolynomialOrder',2

Data Types: double | single

'KernelOffset' — Kernel offset parameter

nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of 'KernelOffset' and a nonnegative scalar.

The software adds `KernelOffset` to each element of the Gram matrix.

The defaults are:

- 0 if the solver is SMO (that is, you set 'Solver', 'SMO')
- 0.1 if the solver is ISDA (that is, you set 'Solver', 'ISDA')

Example: 'KernelOffset',0

Data Types: double | single

'Epsilon' — Half the width of epsilon-insensitive band

$\text{iqr}(Y)/13.49$ (default) | nonnegative scalar value

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of 'Epsilon' and a nonnegative scalar value.

The default `Epsilon` value is $\text{iqr}(Y)/13.49$, which is an estimate of a tenth of the standard deviation using the interquartile range of the response variable Y . If $\text{iqr}(Y)$ is equal to zero, then the default `Epsilon` value is 0.1.

Example: 'Epsilon',0.3

Data Types: single | double

'Standardize' — Flag to standardize predictor data

false (default) | true

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize', true:

- The software centers and scales each column of the predictor data (X) by the weighted column mean and standard deviation, respectively (for details on weighted

standardizing, see “Algorithms” on page 29-2109). MATLAB does not standardize the data contained in the dummy variable columns generated for categorical predictors.

- The software trains the model using the standardized predictor matrix, but stores the unstandardized data in the model property `X`.

Example: `'Standardize', true`

Data Types: `logical`

'Solver' — Optimization routine

`'ISDA' | 'L1QP' | 'SMO'`

Optimization routine, specified as the comma-separated pair consisting of `'Solver'` and a value in this table.

Value	Description
<code>'ISDA'</code>	Iterative Single Data Algorithm (see [30])
<code>'L1QP'</code>	Uses <code>quadprog</code> to implement <i>L1</i> soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license. For more details, see “Quadratic Programming Definition” (Optimization Toolbox).
<code>'SMO'</code>	Sequential Minimal Optimization (see [17])

The defaults are:

- `'ISDA'` if you set `'OutlierFraction'` to a positive value
- `'SMO'` otherwise

Example: `'Solver', 'ISDA'`

Data Types: `char`

'Alpha' — Initial estimates of alpha coefficients

numeric vector

Initial estimates of alpha coefficients, specified as the comma-separated pair consisting of `'Alpha'` and a numeric vector. The length of `Alpha` must be equal to the number of rows of `X`.

- Each element of `Alpha` corresponds to an observation in `X`.
- `Alpha` cannot contain any NaNs.
- If you specify `Alpha` and any one of the cross-validation name-value pair arguments ('`CrossVal`', '`CVPartition`', '`Holdout`', '`KFold`', or '`Leaveout`'), then the software returns an error.

If `Y` contains any missing values, then remove all rows of `Y`, `X`, and `Alpha` that correspond to the missing values. That is, enter:

```
idx = ~isnan(Y);
Y = Y(idx);
X = X(idx,:);
alpha = alpha(idx);
```

Then, pass `Y`, `X`, and `alpha` as the response, predictors, and initial alpha estimates, respectively.

The default is `zeros(size(Y,1))`.

Example: '`Alpha`',`0.1*ones(size(X,1),1)`

Data Types: `single` | `double`

'CacheSize' — Cache size

1000 (default) | '`maximal`' | positive scalar

Cache size, specified as the comma-separated pair consisting of '`CacheSize`' and '`maximal`' or a positive scalar.

If `CacheSize` is '`maximal`', then the software reserves enough memory to hold the entire n -by- n Gram matrix.

If `CacheSize` is a positive scalar, then the software reserves `CacheSize` megabytes of memory for training the model.

Example: '`CacheSize`', '`maximal`'

Data Types: `double` | `char` | `single`

'ClipAlphas' — Flag to clip alpha coefficients

`true` (default) | `false`

Flag to clip alpha coefficients, specified as the comma-separated pair consisting of '`ClipAlphas`' and either `true` or `false`.

Suppose that the alpha coefficient for observation j is α_j and the box constraint of observation j is C_j , $j = 1, \dots, n$. n is the training sample size.

Value	Description
true	At each iteration, if α_j is near 0 or near C_j , then MATLAB sets α_j to 0 or to C_j , respectively.
false	MATLAB does not change the alpha coefficients during optimization.

MATLAB stores the final values of a in the `Alpha` property of the trained SVM model object.

`ClipAlphas` can affect SMO and ISDA convergence.

Example: `'ClipAlphas', false`

Data Types: `logical`

'NumPrint' — Number of iterations between optimization diagnostic message output

1000 (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of `'NumPrint'` and a nonnegative integer.

If you use `'Verbose', 1` and `'NumPrint', numprint`, then the software displays all optimization diagnostic messages from SMO and ISDA every `numprint` iterations in the Command Window.

Example: `'NumPrint', 500`

Data Types: `double` | `single`

'OutlierFraction' — Expected proportion of outliers in training data

0 (default) | numeric scalar in the interval [0,1)

Expected proportion of outliers in training data, specified as the comma-separated pair consisting of `'OutlierFraction'` and a numeric scalar in the interval [0,1). `ftrsvm` removes observations with large gradients, ensuring that `ftrsvm` removes the fraction of observations specified by `OutlierFraction` by the time convergence is reached. This name-value pair is only valid when `'Solver'` is `'ISDA'`.

Example: `'OutlierFraction', 0.1`

Data Types: `single` | `double`

'RemoveDuplicates' — Flag to replace duplicate observations with single observations in training data

false (default) | true

Flag to replace duplicate observations with single observations in the training data, specified as the comma-separated pair consisting of 'RemoveDuplicates' and true or false.

If RemoveDuplicates is true, then fitrsvm replaces duplicate observations in the training data with a single observation of the same value. The weight of the single observation is equal to the sum of the weights of the corresponding removed duplicates (see Weights).

Tip: If your data set contains many duplicate observations, then specifying 'RemoveDuplicates', true can decrease convergence time considerably.

Data Types: logical

'Verbose' — Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either 0, 1, or 2. Verbose controls the amount of optimization information that the software displays in the Command Window and saves as a structure to Mdl.ConvergenceInfo.History.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display or save convergence information.
1	The software displays diagnostic messages and saves convergence criteria every numprint iterations, where numprint is the value of the name-value pair argument 'NumPrint'.
2	The software displays diagnostic messages and saves convergence criteria at every iteration.

Example: `'Verbose',1`

Data Types: `double | single`

Other Regression Options

'CategoricalPredictors' — Categorical predictors list

numeric or logical vector | cell array of character vectors | `'all'`

List of categorical predictors, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following:

- A numeric vector with indices from 1 through `p`, where `p` is the number of columns of `X`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X` is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- `'all'`, meaning all predictors are categorical.

By default, if the predictor data is in a matrix (`X`), `fitrsvm` assumes that none of the predictors are categorical. If the predictor data is in a table (`Tbl`), `fitrsvm` assumes that a variable is categorical if it contains logical values, categorical values, or a cell array of character vectors.

For example, the following syntax specifies that columns 1 and 3 of the input matrix `X` contain categorical variables.

Example: `'CategoricalPredictors',[1,3]`

Data Types: `single | double | logical | cell`

'PredictorNames' — Predictor variable names

cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `'PredictorNames'` to give the predictor variables in `X` names.

- The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
- By default, `PredictorNames` is `{x1,x2,...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitrsvm` uses the predictor variables in `PredictorNames` and the response only in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It good practice to specify the predictors for training using one of `'PredictorNames'` or `formula` only.

Example: `'PredictorNames'`,
`{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `cell`

'ResponseName' — Response variable name

`'Y'` (default) | character vector

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char`

'Weights' — Observation weights

`ones(size(X,1),1)` (default) | vector of numeric values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of numeric values. The size of `Weights` must equal the number of rows in `X`. `fitrsvm` normalizes the values of `Weights` to sum to 1.

Data Types: `single` | `double`

Cross-Validation Options

'CrossVal' — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, you can cross-validate the model later using the `crossval` method.

Example: `'CrossVal','on'`

'CVPartition' — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data

- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify, e.g., `'KFold', k`, then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold', 5`

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout', 'on'`, then, for each of the n observations, where n is `size(Mdl.X, 1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Leaveout', 'on'

Data Types: char

Convergence Controls

'DeltaGradientTolerance' — Tolerance for gradient difference

0 (default) | nonnegative scalar

Tolerance for gradient difference between upper and lower violators obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar.

Example: 'DeltaGradientTolerance', 1e-4

Data Types: single | double

'GapTolerance' — Feasibility gap tolerance

1e-3 (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'GapTolerance' and a nonnegative scalar.

If GapTolerance is 0, then fitrsvm does not use this parameter to check convergence.

Example: 'GapTolerance', 1e-4

Data Types: single | double

'IterationLimit' — Maximal number of numerical optimization iterations

1e6 (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The software returns a trained model regardless of whether the optimization routine successfully converges. Mdl.ConvergenceInfo contains convergence information.

Example: 'IterationLimit', 1e8

Data Types: double | single

'KKTolerance' — Tolerance for KKT violation

0 | nonnegative scalar value

Tolerance for Karush-Kuhn-Tucker (KKT) violation, specified as the comma-separated pair consisting of `'KKTolerance'` and a nonnegative scalar value.

This name-value pair applies only if `'Solver'` is `'SMO'` or `'ISDA'`.

If `KKTolerance` is 0, then `fritsvm` does not use this parameter to check convergence.

Example: `'KKTolerance', 1e-4`

Data Types: `single` | `double`

'ShrinkagePeriod' — Number of iterations between movement of observations from active to inactive set

0 (default) | nonnegative integer

Number of iterations between the movement of observations from the active to inactive set, specified as the comma-separated pair consisting of `'ShrinkagePeriod'` and a nonnegative integer.

If you set `'ShrinkagePeriod', 0`, then the software does not shrink the active set.

Example: `'ShrinkagePeriod', 1000`

Data Types: `double` | `single`

Hyperparameter Optimization

'OptimizeHyperparameters' — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'BoxConstraint', 'KernelScale', 'Epsilon'}`
- `'all'` — Optimize all eligible parameters.
- Cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fritsvm` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note: `OptimizeHyperparameters` values override any values you set using other name-value pairs. For example, setting `OptimizeHyperparameters` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitrsvm` are:

- `BoxConstraint` — `fitrsvm` searches among positive values, by default log-scaled in the range `[1e-3,1e3]`.
- `KernelScale` — `fitrsvm` searches among positive values, by default log-scaled in the range `[1e-3,1e3]`.
- `Epsilon` — `fitrsvm` searches among positive values, by default log-scaled in the range `[1e-3*ResponseIqr/1.349,1e2*ResponseIqr/1.349]`.
- `KernelFunction` — `fitrsvm` searches among `'gaussian'`, `'linear'`, and `'polynomial'`.
- `PolynomialOrder` — `fitrsvm` searches among integers in the range `[2,4]`.
- `Standardize` — `fitrsvm` searches among `'true'` and `'false'`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load carsmall
params = hyperparameters('fitrsvm',[Horsepower,Weight],MPG);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression, and the misclassification rate for classification. To control the iterative display, set the `HyperparameterOptimizationOptions` name-value pair, `Verbose` field. To control the plots, set the `HyperparameterOptimizationOptions` name-value pair, `ShowPlots` field.

For an example, see “Optimize SVM Regression” on page 29-2555.

Example: `'auto'`

Data Types: `char` | `cell`

'HyperparameterOptimizationOptions' — Options for optimization

structure

Options for optimization, specified as a structure. Modifies the effect of the `OptimizeHyperparameters` name-value pair. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the <code>commandsortrows</code> (<code>Mdl.ParameterOptim</code>).</p>	'bayesopt'
AcquisitionFunc	<ul style="list-style-type: none"> 'expected-improvement-per-second-plus' 'expected-improvement' 'expected-improvement-plus' 'expected-improvement-per-second' 'lower-confidence-bound' 'probability-of-improvement' <p>For details, see the <code>bayesopt</code> <code>AcquisitionFunctionName</code> name-value pair, or “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'

Field Name	Values	Default
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
NumGridDivisions	For 'gridsearch', the number of values in each dimension. Can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. Ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , plots the best objective function value against iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is 'bayesopt', then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediateResults	Logical value indicating whether to save results when <code>Optimizer</code> is 'bayesopt'. If <code>true</code> , overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesoptVerbose</code> name-value pair.	1

Field Name	Values	Default
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code>	<code>Kfold = 5</code>
Holdout	A scalar in the range $(0, 1)$ representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example: `struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

Mdl — Trained SVM regression model

RegressionSVM model | RegressionPartitionedSVM cross-validated model

Trained SVM regression model, returned as a RegressionSVM model or RegressionPartitionedSVM cross-validated model.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `Leaveout`, `CrossVal`, or `CVPartition`, then `Mdl` is a RegressionPartitionedSVM cross-validated model. Otherwise, `Mdl` is a RegressionSVM model.

Limitations

`fitrsvm` supports low- through moderate-dimensional data sets. For high-dimensional data set, use `fitrlinear` instead.

Tips

- Unless your data set is large, always try to standardize the predictors (see `Standardize`). Standardization makes predictors insensitive to the scales on which they are measured.
- It is good practice to cross-validate using the `KFold` name-value pair argument. The cross-validation results determine how well the SVM model generalizes.
- Sparsity in support vectors is a desirable property of an SVM model. To decrease the number of support vectors, set the `BoxConstraint` name-value pair argument to a large value. This action also increases the training time.
- For optimal training time, set `CacheSize` as high as the memory limit on your computer allows.
- If you expect many fewer support vectors than observations in the training set, then you can significantly speed up convergence by shrinking the active-set using the name-value pair argument `'ShrinkagePeriod'`. It is good practice to use `'ShrinkagePeriod', 1000`.
- Duplicate observations that are far from the regression line do not affect convergence. However, just a few duplicate observations that occur near the regression line can slow down convergence considerably. To speed up convergence, specify `'RemoveDuplicates', true` if:
 - Your data set contains many duplicate observations.
 - You suspect that a few duplicate observations can fall near the regression line.

However, to maintain the original data set during training, `fitrsvm` must temporarily store separate data sets: the original and one without the duplicate observations. Therefore, if you specify `true` for data sets containing few duplicates, then `fitrsvm` consumes close to double the memory of the original data.

Algorithms

- NaN, <undefined>, and empty character vector (' ') values indicate missing values. `firtsvm` removes entire rows of data corresponding to a missing response. When normalizing weights, `firtsvm` ignores any weight corresponding to an observation with at least one missing predictor. Consequently, observation box constraints might not equal `BoxConstraint`.
- `firtsvm` removes observations that have zero weight.
- If you set `'Standardize', true` and `'Weights',` then `firtsvm` standardizes the predictors using their corresponding weighted means and weighted standard deviations. That is, `firtsvm` standardizes predictor j (x_j) using

$$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.$$

- $$\mu_j^* = \frac{1}{\sum_k w_k} \sum_k w_k x_{jk}.$$
- x_{jk} is observation k (row) of predictor j (column).
- $$(\sigma_j^*)^2 = \frac{v_1}{v_1^2 - v_2} \sum_k w_k (x_{jk} - \mu_j^*)^2.$$
- $$v_1 = \sum_j w_j.$$
- $$v_2 = \sum_j (w_j)^2.$$
- If your predictor data contains categorical variables, then the software generally uses full dummy encoding for these variables. The software creates one dummy variable for each level of each categorical variable.
- The `PredictorNames` property stores one element for each of the original predictor variable names. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then `PredictorNames` is a 1-

by-3 cell array of character vectors containing the original names of the predictor variables.

- The `ExpandedPredictorNames` property stores one element for each of the predictor variables, including the dummy variables. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then `ExpandedPredictorNames` is a 1-by-5 cell array of character vectors containing the names of the predictor variables and the new dummy variables.
- Similarly, the `Beta` property stores one beta coefficient for each predictor, including the dummy variables.
- The `SupportVectors` property stores the predictor values for the support vectors, including the dummy variables. For example, assume that there are m support vectors and three predictors, one of which is a categorical variable with three levels. Then `SupportVectors` is an m -by-5 matrix.
- The `X` property stores the training data as originally input. It does not include the dummy variables. When the input is a table, `X` contains only the columns used as predictors.
- For predictors specified in a table, if any of the variables contain ordered (ordinal) categories, the software uses ordinal encoding for these variables.
 - For a variable having k ordered levels, the software creates $k - 1$ dummy variables. The j th dummy variable is -1 for levels up to j , and +1 for levels $j + 1$ through k .
 - The names of the dummy variables stored in the `ExpandedPredictorNames` property indicate the first level with the value +1. The software stores $k - 1$ additional predictor names for the dummy variables, including the names of levels 2, 3, ..., k .
- All solvers implement $L1$ soft-margin minimization.
- Let p be the proportion of outliers that you expect in the training data. If you set '`OutlierFraction`', p , then the software implements *robust learning*. In other words, the software attempts to remove 100 p % of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.

Introduced in R2015b

fitrtree

Fit binary regression decision tree

Syntax

```
tree = fitrtree(Tbl,ResponseVarName)
tree = fitrtree(Tbl,formula)
tree = fitrtree(Tbl,Y)
```

```
tree = fitrtree(X,Y)
```

```
tree = fitrtree( ____,Name,Value)
```

Description

`tree = fitrtree(Tbl,ResponseVarName)` returns a regression tree based on the input variables (also known as predictors, features, or attributes) in the table `Tbl` and output (response) contained in `Tbl.ResponseVarName`. `tree` is a binary tree where each branching node is split based on the values of a column of `Tbl`.

`tree = fitrtree(Tbl,formula)` returns a regression tree based on the input variables contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `tree`.

`tree = fitrtree(Tbl,Y)` returns a regression tree based on the input variables contained in the table `Tbl` and output in vector `Y`.

`tree = fitrtree(X,Y)` returns a regression tree based on the input variables `X` and output `Y`. `tree` is a binary tree where each branching node is split based on the values of a column of `X`.

`tree = fitrtree(____,Name,Value)` fits a tree with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify observation weights or train a cross-validated model.

Examples

Construct a Regression Tree

Load the sample data.

```
load carsmall;
```

Construct a regression tree using the sample data.

```
tree = fitrtree([Weight, Cylinders],MPG,...  
               'categoricalpredictors',2,'MinParentSize',20,...  
               'PredictorNames',{'W','C'})
```

```
tree =
```

```
RegressionTree  
    PredictorNames: {'W' 'C'}  
    ResponseName: 'Y'  
    CategoricalPredictors: 2  
    ResponseTransform: 'none'  
    NumObservations: 94
```

Predict the mileage of 4,000-pound cars with 4, 6, and 8 cylinders.

```
mileage4K = predict(tree,[4000 4; 4000 6; 4000 8])
```

```
mileage4K =
```

```
    19.2778  
    19.2778  
    14.3889
```

Control Regression Tree Depth

You can control the depth of trees using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters. `fitrtree` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

The default values of the tree-depth controllers for growing regression trees are:

- `n - 1` for `MaxNumSplits`. `n` is the training sample size.
- `1` for `MinLeafSize`.
- `10` for `MinParentSize`.

These default values tend to grow deep trees for large training sample sizes.

Train a regression tree using the default values for tree-depth control. Cross validate the model using 10-fold cross validation.

```
rng(1); % For reproducibility
MdlDefault = fitrtree(X,MPG,'CrossVal','on');
```

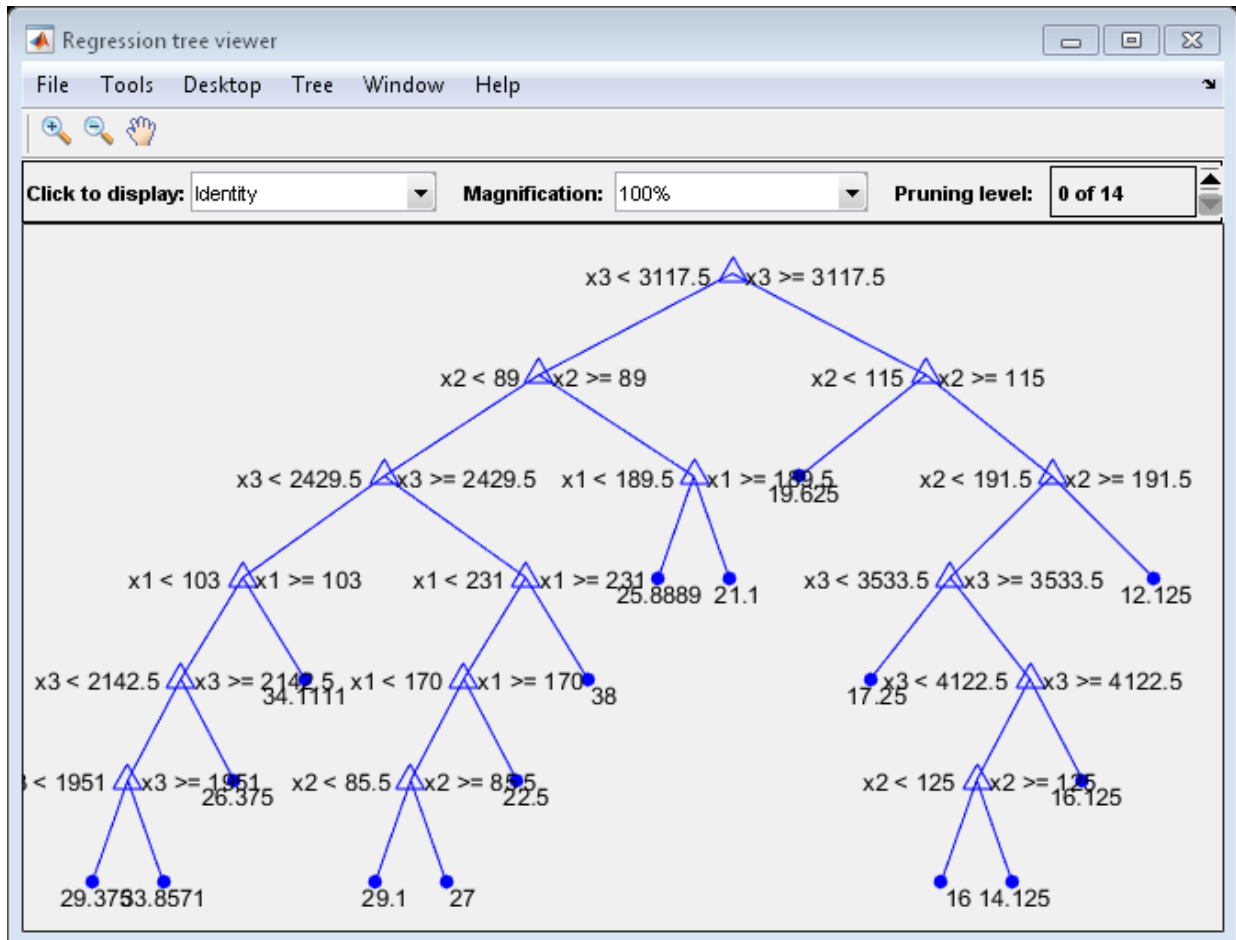

Draw a histogram of the number of imposed splits on the trees. The number of imposed splits is one less than the number of leaves. Also, view one of the trees.

```
numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, MdlDefault.Trained);

figure;
histogram(mdlDefaultNumSplits)

view(MdlDefault.Trained{1}, 'Mode', 'graph')
```

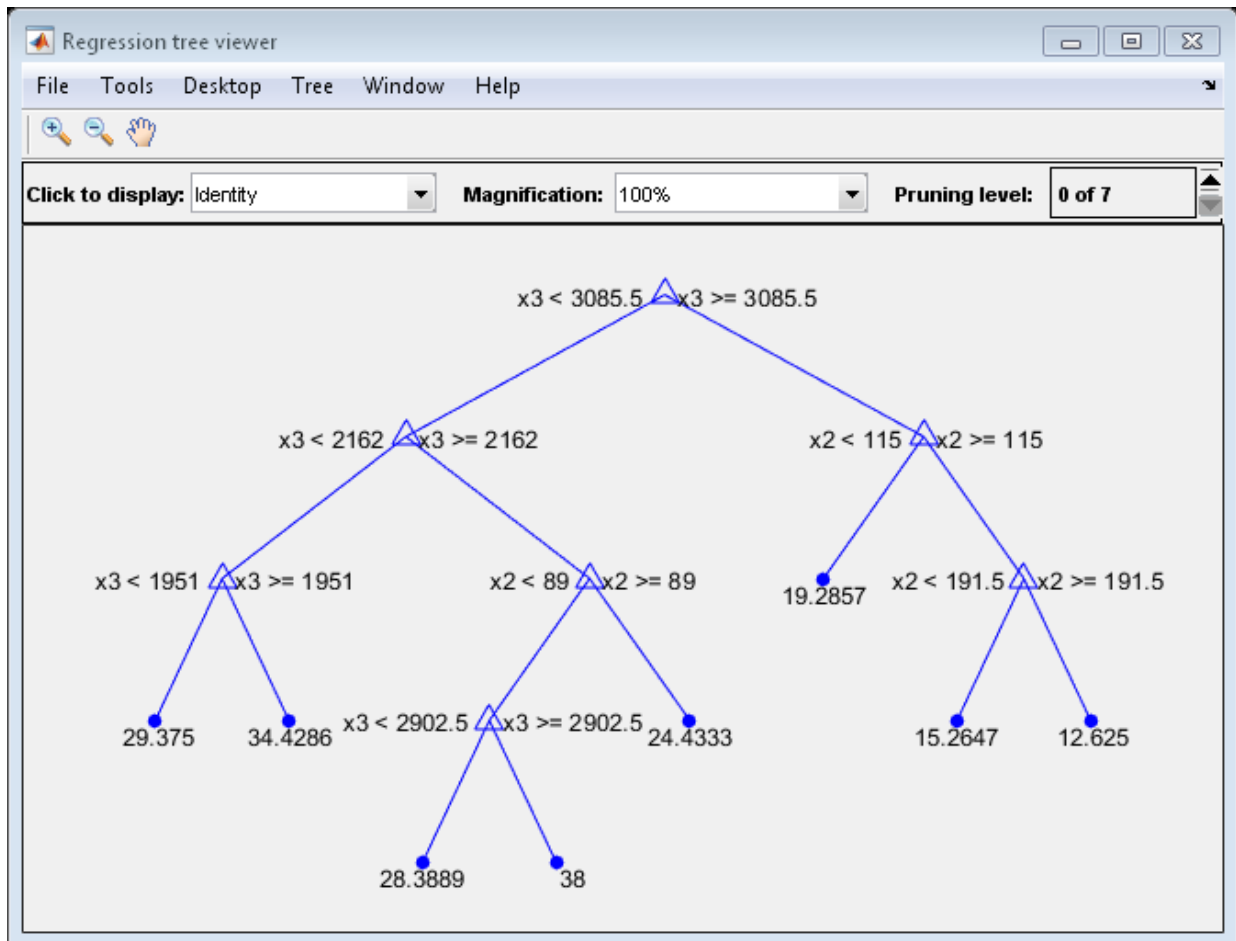

The average number of splits is between 14 and 15.

Suppose that you want a regression tree that is not as complex (deep) as the ones trained using the default number of splits. Train another regression tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default regression tree. Cross validate the model using 10-fold cross validation.

```
Md17 = fitrtree(X,MPG,'MaxNumSplits',7,'CrossVal','on');
view(Md17.Trained{1},'Mode','graph')
```

Compare the cross validation MSEs of the models.

```
mseDefault = kfoldLoss(MdlDefault)
mse7 = kfoldLoss(Mdl7)
```

```
mseDefault =
    27.7277
```

```
mse7 =
    28.3833
```

Mdl7 is much less complex and performs only slightly worse than MdlDefault.

Optimize Regression Tree

This example shows how to optimize hyperparameters automatically using `fitrtree`. The example uses the `carsmall` data.

Load the `carsmall` data.

```
load carsmall
```

Use `Weight` and `Horsepower` as predictors for `MPG`. Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
X = [Weight,Horsepower];
Y = MPG;
rng default
Mdl = fitrtree(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
    'expected-improvement-plus'))
```

      ResponseTransform: 'none'  
      NumObservations: 94  
      HyperparameterOptimizationResults: [1×1 BayesianOptimization]
```

Unbiased Predictor Importance Estimates

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
          Model_Year,Weight,MPG);
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))
numMfg = numel(categories(Mfg))
numModelYear = numel(categories(Model_Year))
```

```
numCylinders =
```

```
3
```

```
numMfg =
```

```
28
```

```
numModelYear =
```

```
3
```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a regression tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits.

```
Mdl = fitrtree(X,'MPG','PredictorSelection','curvature','Surrogate','on');
```

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

```
imp = predictorImportance(Mdl);
```

```
figure;  
bar(imp);  
title('Predictor Importance Estimates');  
ylabel('Estimates');  
xlabel('Predictors');  
h = gca;  
h.XTickLabel = Mdl.PredictorNames;  
h.XTickLabelRotation = 45;  
h.TickLabelInterpreter = 'none';
```

In this case, `Displacement` is the most important predictor, followed by `Horsepower`.

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector. For example, if `Tbl` stores the response variable `Y` as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

formula — Explanatory model of response and subset of predictor variables

character vector

Explanatory model of the response and a subset of the predictor variables, specified as a character vector in the form of `'Y-X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char`

Y — Response data

numeric column vector

Response data, specified as a numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

The software considers NaN values in `Y` to be missing values. `fitrtree` does not use observations with missing values for `Y` in the fit.

Data Types: `single` | `double`

X — Predictor data

numeric matrix

Predictor data, specified as numeric matrix. Each column of `X` represents one variable, and each row represents one observation.

`fitrtree` considers NaN values in `X` as missing values. `fitrtree` does not use observations with all missing values for `X` the fit. `fitrtree` uses observations with some missing values for `X` to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note: You cannot use any cross-validation name-value pair along with `OptimizeHyperparameters`. You can modify the cross-validation for `OptimizeHyperparameters` only by using the `HyperparameterOptimizationOptions` name-value pair.

Example: 'CrossVal', 'on', 'MinParentSize', 30 specifies a cross-validated regression tree with a minimum of 30 observations per branch node.

Model Parameters

'CategoricalPredictors' — Categorical predictors list

numeric or logical vector | cell array of character vectors | character matrix | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- A numeric vector with indices from 1 through p , where p is the number of columns of X .
- A logical vector of length p , where a `true` entry means that the corresponding column of X is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

By default, if the predictor data is in a matrix (X), the software assumes that none of the predictors are categorical. If the predictor data is in a table (`Tbl`), the software assumes that a variable is categorical if it contains, logical values, values of the unordered data type `categorical`, or a cell array of character vectors.

Example: 'CategoricalPredictors', 'all'

Data Types: `single` | `double` | `char` | `logical` | `cell`

'MergeLeaves' — Leaf merge flag

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and 'on' or 'off'.

If `MergeLeaves` is 'on', then `fitrtree`:

- Merges leaves that originate from the same parent node, and that yields a sum of risk values greater or equal to the risk associated with the parent node

- Estimates the optimal sequence of pruned subtrees, but does not prune the regression tree

Otherwise, `fitrtree` does not merge leaves.

Example: `'MergeLeaves', 'off'`

'MinParentSize' — Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of `'MinParentSize'` and a positive integer value. Each branch node in the tree has at least `MinParentSize` observations. If you supply both `MinParentSize` and `MinLeafSize`, `fitrtree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize, 2*MinLeafSize)`.

Example: `'MinParentSize', 8`

Data Types: `single` | `double`

'PredictorNames' — Predictor variable names

cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `'PredictorNames'` to give the predictor variables in `X` names.
 - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
 - By default, `PredictorNames` is `{x1,x2,...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitrtree` uses the predictor variables in `PredictorNames` and the response only in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.

- It good practice to specify the predictors for training using one of 'PredictorNames' or formula only.

```
Example: 'PredictorNames',
{'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth'}
```

Data Types: cell

'PredictorSelection' — Algorithm used to select the best split predictor

'allsplits' (default) | 'curvature' | 'interaction-curvature'

Algorithm used to select the best split predictor at each node, specified as the comma-separated pair consisting of 'PredictorSelection' and a value in this table.

Value	Description
'allsplits'	Standard CART — Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors [1].
'curvature'	Curvature test — Selects the split predictor that minimizes the p -value of chi-square tests of independence between each predictor and the response [2]. Training speed is similar to standard CART.
'interaction-curvature'	Interaction test — Chooses the split predictor that minimizes the p -value of chi-square tests of independence between each predictor and the response (that is, conducts curvature tests), and that minimizes the p -value of a chi-square test of independence between each pair of predictors and response [2]. Training speed can be slower than standard CART.

For 'curvature' and 'interaction-curvature', if all tests yield p -values greater than 0.05, then fitree stops splitting nodes.

Tip:

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [3]. Consider specifying the curvature or interaction test if any of the following are true:

- If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
 - If an analysis of predictor importance is your goal. For more on predictor importance estimation, see `predictorImportance`.
 - Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test .
 - Prediction speed is unaffected by the value of `'PredictorSelection'`.
-

For details on how `fitrtree` selects split predictors, see “Node Splitting Rules” on page 29-2613.

Example: `'PredictorSelection', 'curvature'`

Data Types: char

'Prune' — Flag to estimate optimal sequence of pruned subtrees

`'on'` (default) | `'off'`

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of `'Prune'` and `'on'` or `'off'`.

If `Prune` is `'on'`, then `fitrtree` grows the regression tree and estimates the optimal sequence of pruned subtrees, but does not prune the regression tree. Otherwise, `fitrtree` grows the regression tree without estimating the optimal sequence of pruned subtrees.

To prune a trained regression tree, pass the regression tree to `prune`.

Example: `'Prune', 'off'`

'PruneCriterion' — Pruning criterion

`'mse'` (default)

Pruning criterion, specified as the comma-separated pair consisting of `'PruneCriterion'` and `'mse'`.

'QuadraticErrorTolerance' — Quadratic error tolerance

1e-6 (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QuadraticErrorTolerance' and a positive scalar value. Splitting nodes stops when quadratic error per node drops below $\text{QuadraticErrorTolerance} \times \text{QED}$, where QED is the quadratic error for the entire data computed before the decision tree is grown.

Example: 'QuadraticErrorTolerance', 1e-4

'ResponseName' — Response variable name

'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName', 'response'

Data Types: char

'ResponseTransform' — Response transform function

'none' (default) | function handle

Response transform function for transforming the raw response values, specified as the comma-separated pair consisting of 'ResponseTransform' and either a function handle or 'none'. The function handle must accept a matrix of response values and return a matrix of the same size. The default is 'none', which means $@(x)x$, or no transformation.

Add or change a ResponseTransform function using dot notation:

```
tree.ResponseTransform = @function
```

Data Types: function_handle

'SplitCriterion' — Split criterion

'MSE' (default)

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.

Example: `'SplitCriterion', 'MSE'`

'Surrogate' — Surrogate decision splits flag

`'off'` (default) | `'on'` | `'all'` | positive integer

Surrogate decision splits flag, specified as the comma-separated pair consisting of `'Surrogate'` and `'on'`, `'off'`, `'all'`, or a positive integer.

- When `'on'`, `fitrtree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer, `fitrtree` finds at most the specified number of surrogate splits at each branch node.
- When set to `'all'`, `fitrtree` finds all surrogate splits at each branch node. The `'all'` setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: `'Surrogate', 'on'`

Data Types: `single` | `double` | `char`

'Weights' — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values. The software weights the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector. For example, if weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors when training the model.

`fitrtree` normalizes the weights in each class to add up to 1.

Data Types: `single` | `double`

Cross Validation

'CrossVal' — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', `fitree` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. You can only use one of these four options ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate `tree` later using the `crossval` method.

Example: 'CrossVal', 'on'

'CVPartition' — Partition for cross-validation tree

cvpartition object

Partition for cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`.

If you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

'Holdout' — Fraction of data for holdout validation

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout', 0.1

Data Types: single | double

'KFold' — Number of folds

10 (default) | positive integer greater than 1

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold',8

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout', 'on'

Hyperparameters

'MaxNumSplits' — Maximal number of decision splits

size(X,1) - 1 (default) | positive integer

Maximal number of decision splits (or branch nodes), specified as the comma-separated pair consisting of 'MaxNumSplits' and a positive integer. `fitrtree` splits `MaxNumSplits` or fewer branch nodes. For more details on splitting behavior, see “Tree Depth Control” on page 29-2616.

Example: 'MaxNumSplits',5

Data Types: single | double

'MinLeafSize' — Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeafSize' and a positive integer value. Each leaf has at least `MinLeafSize` observations per tree leaf. If you supply both `MinParentSize` and `MinLeafSize`, `fitrtree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize, 2*MinLeafSize)`.

Example: `'MinLeafSize',3`

Data Types: `single` | `double`

'NumVariablesToSample' — Number of predictors for split

`'all'` (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NumVariablesToSample'` and a positive integer value. You can also specify `'all'` to use all available predictors.

Example: `'NumVariablesToSample',3`

Data Types: `single` | `double`

Hyperparameter Optimization

'OptimizeHyperparameters' — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'MinLeafSize'}`.
- `'all'` — Optimize all eligible parameters.
- Cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitree` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note: `OptimizeHyperparameters` values override any values you set using other name-value pairs. For example, setting `OptimizeHyperparameters` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitree` are:

- `MaxNumSplits` — `fitrtree` searches among integers, by default log-scaled in the range `[1,max(2,NumObservations-1)]`.
- `MinLeafSize` — `fitrtree` searches among integers, by default log-scaled in the range `[1,max(2,floor(NumObservations/2))]`.
- `NumVariablesToSample` — `fitrtree` does not optimize over this hyperparameter. If you pass `NumVariablesToSample` as a parameter name, `fitrtree` simply uses the full number of predictors. However, `fitrensemble` does optimize over this hyperparameter.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load carsmall
params = hyperparameters('fitrtree',[Horsepower,Weight],MPG);
params(1).Range = [1,30];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression, and the misclassification rate for classification. To control the iterative display, set the `HyperparameterOptimizationOptions` name-value pair, `Verbose` field. To control the plots, set the `HyperparameterOptimizationOptions` name-value pair, `ShowPlots` field.

For an example, see “Optimize Regression Tree” on page 29-2588.

Example: 'auto'

Data Types: char | cell

'HyperparameterOptimizationOptions' — Options for optimization structure

Options for optimization, specified as a structure. Modifies the effect of the `OptimizeHyperparameters` name-value pair. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	• 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code> .	'bayesopt'

Field Name	Values	Default
	<ul style="list-style-type: none"> 'gridsearch' — Use grid search with NumGridDivisions values per dimension. 'randomsearch' — Search at random among MaxObjectiveEvaluations points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the <code>commandsortrows(Mdl.ParameterOptim.</code></p>	
AcquisitionFunc	<ul style="list-style-type: none"> 'expected-improvement-per-second-plus' 'expected-improvement' 'expected-improvement-plus' 'expected-improvement-per-second' 'lower-confidence-bound' 'probability-of-improvement' <p>For details, see the <code>bayesopt</code> AcquisitionFunctionName name-value pair, or “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEva	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'

Field Name	Values	Default
NumGridDivision	For 'gridsearch', the number of values in each dimension. Can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. Ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , plots the best objective function value against iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is 'bayesopt', then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediate	Logical value indicating whether to save results when <code>Optimizer</code> is 'bayesopt'. If <code>true</code> , overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesoptVerbose</code> name-value pair.	1

Field Name	Values	Default
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code>	<code>Kfold = 5</code>
Holdout	A scalar in the range $(0, 1)$ representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example: `struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

tree — Regression tree

regression tree object

Regression tree, returned as a regression tree object. Using the `'Crossval'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a tree of class `RegressionPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

Definitions

Curvature Test

The *curvature test* is a statistical test assessing the null hypothesis that two variables are unassociated.

The curvature test between predictor variable x and y is conducted using this process.

- 1 If x is continuous, then partition it into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.
- 2 For each level in the partitioned predictor $j = 1 \dots J$ and class in the response $k = 1, \dots, K$, compute the weighted proportion of observations in class k

$$\hat{\pi}_{jk} = \sum_{i=1}^n I\{y_i = k\} w_i.$$

w_i is the weight of observation i , $\sum w_i = 1$, I is the indicator function, and n is the sample size. If all observations have the same weight, then $\hat{\pi}_{jk} = \frac{n_{jk}}{n}$, where n_{jk} is the number of observations in level j of the predictor that are in class k .

- 3 Compute the test statistic

$$t = n \sum_{k=1}^K \sum_{j=1}^J \frac{(\hat{\pi}_{jk} - \hat{\pi}_{j+} \hat{\pi}_{+k})^2}{\hat{\pi}_{j+} \hat{\pi}_{+k}}$$

$\hat{\pi}_{j+} = \sum_k \hat{\pi}_{jk}$, that is, the marginal probability of observing the predictor at level

j . $\hat{\pi}_{+k} = \sum_j \hat{\pi}_{jk}$, that is the marginal probability of observing class k . If n is large

enough, then t is distributed as a χ^2 with $(K - 1)(J - 1)$ degrees of freedom.

- 4 If the p -value for the test is less than 0.05, then reject the null hypothesis that there is no association between x and y .

When determining the best split predictor at each node, the standard CART algorithm prefers to select continuous predictors that have many levels. Sometimes, such a selection can be spurious and can also mask more important predictors that have fewer levels, such as categorical predictors.

The curvature test can be applied instead of standard CART to determine the best split predictor at each node. In that case, the best split predictor variable is the one that minimizes the significant p -values (those less than 0.05) of curvature tests between each predictor and the response variable. Such a selection is robust to the number of levels in individual predictors.

For more details on how the curvature test applies to growing regression trees, see “Node Splitting Rules” on page 29-2613 and [3].

Interaction Test

The *interaction test* is a statistical test that assesses the null hypothesis that there is no interaction between a pair of predictor variables and the response variable.

The interaction test assessing the association between predictor variables x_1 and x_2 with respect to y is conducted using this process.

- 1 If x_1 or x_2 is continuous, then partition that variable into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.
- 2 Create the nominal variable z with $J = J_1 J_2$ levels that assigns an index to observation i according to which levels of x_1 and x_2 it belongs. Remove any levels of z that do not correspond to any observations.
- 3 Conduct a curvature test between z and y .

When growing decision trees, if there are important interactions between pairs of predictors, but there are also many other less important predictors in the data, then standard CART tends to miss the important interactions. However, conducting curvature and interaction tests for predictor selection instead can improve detection of important interactions, which can yield more accurate decision trees.

For more details on how the interaction test applies to growing decision trees, see “Curvature Test” on page 29-2610, “Node Splitting Rules” on page 29-2613 and [2].

Predictive Measure of Association

The *predictive measure of association* is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_j L_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_j R_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Surrogate Decision Splits

A *surrogate decision split* is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate

predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association.

Tip

By default, `Prune` is 'on'. However, this specification does not prune the regression tree. To prune a trained regression tree, pass the regression tree to `prune`.

Algorithms

Node Splitting Rules

`fitree` uses these processes to determine how to split node t .

- For standard CART (that is, if `PredictorSelection` is 'allpairs') and for all predictors x_i , $i = 1, \dots, p$:
 - 1 `fitree` computes the weighted, mean-square error (MSE) of the responses in node t using

$$\varepsilon_t = \sum_{j \in T} w_j (y_j - \bar{y}_t)^2.$$

w_j is the weight of observation j , and T is the set of all observation indices in node t . If you do not specify `Weights`, then $w_j = 1/n$, where n is the sample size.

- 2 `fitree` estimates the probability that an observation is in node t using

$$P(T) = \sum_{j \in T} w_j.$$

- 3 `fitree` sorts x_i in ascending order. Each element of the sorted predictor is a splitting candidate or cut point. `fitree` records any indices corresponding to missing values in the set T_U , which is the unsplit set.
- 4 `fitree` determines the best way to split node t using x_i by maximizing the reduction in MSE (ΔI) over all splitting candidates. That is, for all splitting candidates in x_i :

- a `fitrtree` splits the observations in node t into left and right child nodes (t_L and t_R , respectively).
- b `fitrtree` computes ΔI . Suppose that for a particular splitting candidate, t_L and t_R contain observation indices in the sets T_L and T_R , respectively.
 - If x_i does not contain any missing values, then the reduction in MSE for the current splitting candidate is

$$\Delta I = P(T)\varepsilon_t - P(T_L)\varepsilon_{t_L} - P(T_R)\varepsilon_{t_R}.$$

- If x_i contains missing values, then, assuming that the observations are missing at random, the reduction in MSE is

$$\Delta I_U = P(T - T_U)\varepsilon_t - P(T_L)\varepsilon_{t_L} - P(T_R)\varepsilon_{t_R}.$$

$T - T_U$ is the set of all observation indices in node t that are not missing.

- If you use surrogate decision splits, then:
 - i `fitrtree` computes the predictive measures of association between the decision split $x_j < u$ and all possible decision splits $x_k < v$, $j \neq k$.
 - ii `fitrtree` sorts the possible alternative decision splits in descending order by their predictive measure of association with the optimal split. The surrogate split is the decision split yielding the largest measure.
 - iii `fitrtree` decides the child node assignments for observations with a missing value for x_i using the surrogate split. If the surrogate predictor also contains a missing value, then `fitrtree` uses the decision split with the second largest measure, and so on, until there are no other surrogates. It is possible for `fitrtree` to split two different observations at node t using two different surrogate splits. For example, suppose the predictors x_1 and x_2 are the best and second best surrogates, respectively, for the predictor x_i , $i \notin \{1, 2\}$, at node t . If observation m of predictor x_i is missing (i.e., x_{mi} is missing), but x_{m1} is not missing, then x_1 is the surrogate predictor for observation x_{mi} . If observations $x_{(m+1),i}$ and $x_{(m+1),1}$ are missing, but $x_{(m+1),2}$ is not missing, then x_2 is the surrogate predictor for observation $m+1$.

- iv `fitree` uses the appropriate MSE reduction formula. That is, if `fitree` fails to assign all missing observations in node t to children nodes using surrogate splits, then the MSE reduction is ΔI_U . Otherwise, `fitree` uses ΔI for the MSE reduction.

- c `fitree` chooses the candidate that yields the largest MSE reduction.

`fitree` splits the predictor variable at the cut point that maximizes the MSE reduction.

- For the curvature test (that is, if `PredictorSelection` is 'curvature'):
 - 1 `fitree` computes the residuals $r_{ti} = y_{ti} - \bar{y}_t$ for all observations in node t .

$$\bar{y}_t = \frac{1}{\sum_i w_i} \sum_i w_i y_{ti},$$

which is the weighted average of the responses in node t .

The weights are the observation weights in `Weights`.

- 2 `fitree` assigns observations to one of two bins according to the sign of the corresponding residuals. Let z_t be a nominal variable that contains the bin assignments for the observations in node t .
- 3 `fitree` conducts curvature tests between each predictor and z_t . For regression trees, $K = 2$.
 - If all p -values are at least 0.05, then `fitree` does not split node t .
 - If there is a minimal p -value, then `fitree` chooses the corresponding predictor to split node t .
 - If more than one p -value is zero due to underflow, then `fitree` applies standard CART to the corresponding predictors to choose the split predictor.
- 4 If `fitree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

For the interaction test (that is, if `PredictorSelection` is 'interaction-curvature'):

- 1 For observations in node t , `fitree` conducts curvature tests between each predictor and the response and interaction tests between each pair of predictors and the response.
 - If all p -values are at least 0.05, then `fitree` does not split node t .

- If there is a minimal p -value and it is the result of a curvature test, then `fitrtree` chooses the corresponding predictor to split node t .
 - If there is a minimal p -value and it is the result of an interaction test, then `fitrtree` chooses the split predictor using standard CART on the corresponding pair of predictors.
 - If more than one p -value is zero due to underflow, then `fitrtree` applies standard CART to the corresponding predictors to choose the split predictor.
- 2 If `fitrtree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

Tree Depth Control

- If `MergeLeaves` is 'on' and `PruneCriterion` is 'mse' (which are the default values for these name-value pair arguments), then the software applies pruning only to the leaves and by using MSE. This specification amounts to merging leaves coming from the same parent node whose MSE is at most the sum of the MSE of its two leaves.
- To accommodate `MaxNumSplits`, `fitrtree` splits all nodes in the current *layer*, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds `MaxNumSplits`, `fitrtree` follows this procedure:
 - 1 Determine how many branch nodes in the current layer must be unsplit so that there are at most `MaxNumSplits` branch nodes.
 - 2 Sort the branch nodes by their impurity gains.
 - 3 Unsplit the number of least successful branches.
 - 4 Return the decision tree grown so far.

This procedure produces maximally balanced trees.

- The software splits branch nodes layer by layer until at least one of these events occurs:
 - There are `MaxNumSplits` branch nodes.
 - A proposed split causes the number of observations in at least one branch node to be fewer than `MinParentSize`.
 - A proposed split causes the number of observations in at least one leaf node to be fewer than `MinLeafSize`.

- The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see `PruneCriterion`), does not improve for all proposed splits in a layer). A special case is when all nodes are pure (i.e., all observations in the node have the same class).
- For values `'curvature'` or `'interaction-curvature'` of `PredictorSelection`, all tests yield p -values greater than 0.05.

`MaxNumSplits` and `MinLeafSize` do not affect splitting at their default values. Therefore, if you set `'MaxNumSplits'`, splitting might stop due to the value of `MinParentSize`, before `MaxNumSplits` splits occur.

Parallelization

For dual-core systems and above, `fitree` parallelizes training decision trees using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

fitSVMPosterior

Fit posterior probabilities

Syntax

```
ScoreSVMModel = fitSVMPosterior(SVMModel)

ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,ResponseVarName)
ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,Y)

ScoreSVMModel = fitSVMPosterior(SVMModel,X,Y)

ScoreSVMModel = fitSVMPosterior( __ ,Name,Value)

[ScoreSVMModel,ScoreTransform] = fitSVMPosterior( __ )
```

Description

`ScoreSVMModel = fitSVMPosterior(SVMModel)` returns `ScoreSVMModel`, which is a trained, support vector machine (SVM) classifier containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMModel`, and by cross validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`). The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function.
- If the classes are perfectly separable, the transformation function is the step function.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function. `fitSVMPosterior` is not appropriate for one-class learning.
- If `SVMModel` is a `ClassificationSVM` classifier, then the software estimates the optimal transformation function by 10-fold cross validation as outlined in [1].

Otherwise, `SVMModel` must be a `ClassificationPartitionedModel` classifier. `SVMModel` specifies the cross-validation method.

- The software stores the optimal transformation function in `ScoreSVMModel.ScoreTransform`.

`ScoreSVMModel = fitSVMPosterior(SVMModel, TBL, ResponseVarName)` returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMModel`. The software estimates the score transformation function using predictor data in the table `TBL` and class labels `TBL.ResponseVarName`.

`ScoreSVMModel = fitSVMPosterior(SVMModel, TBL, Y)` returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMModel`. The software estimates the score transformation function using predictor data in the table `TBL` and class labels `Y`.

`ScoreSVMModel = fitSVMPosterior(SVMModel, X, Y)` returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMModel`. The software estimates the score transformation function using predictor data `X` and class labels `Y`.

`ScoreSVMModel = fitSVMPosterior(____, Name, Value)` uses additional options specified by one or more `Name, Value` pair arguments provided `SVMModel` is a `ClassificationSVM` classifier. For example, you can specify the number of folds to use in k -fold cross validation.

`[ScoreSVMModel, ScoreTransform] = fitSVMPosterior(____)` additionally returns the transformation function parameters (`ScoreTransform`) using any of the input arguments in the previous syntaxes.

Examples

Fit the Score-to-Posterior Probability Function for Separable Classes

Load Fisher's iris data set. Train the classifier using the petal lengths and widths, and remove the virginica species from the data.

```
load fisheriris
classKeep = ~strcmp(species, 'virginica');
X = meas(classKeep, 3:4);
y = species(classKeep);
```

```
gscatter(X(:,1),X(:,2),y);  
title('Scatter Diagram of Iris Measurements')  
xlabel('Petal length')  
ylabel('Petal width')  
legend('Setosa','Versicolor')
```

The classes are perfectly separable. Therefore, the score transformation function is a step function.

Train an SVM classifier using the data. Cross validate the classifier using 10-fold cross validation (the default).

```
rng(1);  
CVSVMModel = fitcsvm(X,y,'CrossVal','on');
```

CVSVMModel is a trained ClassificationPartitionedModel SVM classifier.

Estimate the step function that transforms scores to posterior probabilities.

```
[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);
```

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

fitSVMPosterior does the following:

- Uses the data that the software stored in CVSVMModel to fit the transformation function
- Warns whenever the classes are separable
- Stores the step function in ScoreCVSVMModel.ScoreTransform

Display the score function type and its parameter values.

ScoreParameters

```
ScoreParameters =
    struct with fields:
        Type: 'step'
        LowerBound: -0.8431
        UpperBound: 0.6897
        PositiveClassProbability: 0.5000
```

ScoreParameters is a structure array with four fields:

- The score transformation function type (Type)
- The score corresponding to the negative class boundary (LowerBound)
- The score corresponding to the positive class boundary (UpperBound)
- The positive class probability (PositiveClassProbability)

Since the classes are separable, the step function transforms the score to either 0 or 1, which is the posterior probability that an observation is a versicolor iris.

Fit the Score-to-Posterior Probability Function for Inseparable Classes

Load the ionosphere data set.

```
load ionosphere
```

The classes of this data set are not separable.

Train an SVM classifier. Cross validate using 10-fold cross validation (the default). It is good practice to standardize the predictors and specify the class order.

```
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'ClassNames',{ 'b', 'g'}, 'Standardize', true, ...
    'CrossVal', 'on');
ScoreTransform = CVSVMModel.ScoreTransform
```

```
ScoreTransform =
    'none'
```

CVSVMModel is a trained ClassificationPartitionedModel SVM classifier. The positive class is 'g'. The ScoreTransform property is none.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```
[ScoreCVSVMModel, ScoreParameters] = fitSVMPosterior(CVSVMModel);
ScoreTransform = ScoreCVSVMModel.ScoreTransform
ScoreParameters
```

```
ScoreTransform =
    '@(S)sigmoid(S,-9.481576e-01,-1.218300e-01)'
```

```
ScoreParameters =
    struct with fields:
        Type: 'sigmoid'
        Slope: -0.9482
        Intercept: -0.1218
```

ScoreTransform is the optimal score transform function. ScoreParameters contains the score transformation function, slope estimate, and the intercept estimate.

You can estimate test-sample, posterior probabilities by passing `ScoreCVSVMModel` to `kfoldPredict`.

Estimate Posterior Probabilities for Test Samples

Estimate positive class posterior probabilities for the test set of an SVM algorithm.

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Specify a 20% holdout sample. It is good practice to standardize the predictors and specify the class order.

```
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Holdout',0.2,'Standardize',true,...
    'ClassNames',{'b','g'});
```

`CVSVMModel` is a trained `ClassificationPartitionedModel` cross-validated classifier.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```
ScoreCVSVMModel = fitSVMPosterior(CVSVMModel);
```

`ScoreSVMModel` is a trained `ClassificationPartitionedModel` cross-validated classifier containing the optimal score transformation function estimated from the training data.

Estimate the out-of-sample positive class posterior probabilities. Display the results for the first 10 out-of-sample observations.

```
[~,OOSPostProbs] = kfoldPredict(ScoreCVSVMModel);
indx = ~isnan(OOSPostProbs(:,2));
hoObs = find(indx); % Holdout observation numbers
OOSPostProbs = [hoObs, OOSPostProbs(indx,2)];
table(OOSPostProbs(1:10,1),OOSPostProbs(1:10,2),...
    'VariableNames',{'ObservationIndex','PosteriorProbability'})
```

```
ans =
```

10×2 table

ObservationIndex	PosteriorProbability
6	0.17378
7	0.89637
8	0.0076609
9	0.91602
16	0.026718
22	4.6081e-06
23	0.9024
24	2.4129e-06
38	0.00042697
41	0.86427

Input Arguments

SVMMODEL — Trained SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier |
ClassificationPartitionedModel classifier

Trained SVM classifier, specified as a ClassificationSVM, CompactClassificationSVM, or ClassificationPartitionedModel classifier.

If SVMMODEL is a ClassificationSVM classifier, then you can set optional name-value pair arguments.

If SVMMODEL is a CompactClassificationSVM classifier, then you must input predictor data X and class labels Y.

TBL — Sample data

table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train SVMMODEL. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train `SVMModel`, then you do not need to specify `ResponseVarName` or `Y`.

If you trained `SVMModel` using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: `table`

X — Predictor data
matrix

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows of X must be equal.

If you set `'Standardize', true` in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of X using the corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`. If the software fits the transformation-function parameter estimates using standardized data, then the estimates might differ from estimation without standardized data.

Data Types: `double` | `single`

ResponseVarName — Response variable name
name of a variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train `SVMModel`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector. For example, if the response variable is stored as `TBL.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of TBL, including `TBL.Response`, as predictors.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

If Y is a character array, then each element must correspond to one class label.

The length of Y and the number of rows of X must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: 'KFold', 8 performs 8-fold cross validation when **SVMModel** is a **ClassificationSVM** classifier.

'CVPartition' — Cross-validation partition

[] (default) | **cvpartition** partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of 'CVPartition' and a **cvpartition** partition as created by **cvpartition**. You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

crossval splits the data into subsets using **cvpartition**.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Holdout', 0.1

Data Types: double | single

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'KFold', 8

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross validation to compute the transformation function, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Use leave-one-out cross validation by using 'on'.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Leaveout', 'on'

Output Arguments

ScoreSVMModel — Trained SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier |
ClassificationPartitionedModel classifier

Trained SVM classifier containing the estimated score transformation function, returned as a ClassificationSVM, CompactClassificationSVM, or ClassificationPartitionedModel classifier.

The `ScoreSVMModel` classifier type is the same as the `SVMModel` classifier type.

To estimate posterior probabilities, pass `ScoreSVMModel` and predictor data to `predict`. If you set `'Standardize', true` in `fitsvm` to train `SVMModel`, then `predict` standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`.

ScoreTransform — Optimal score-to-posterior-probability transformation function parameters

structure array

Optimal score-to-posterior-probability transformation function parameters, specified as a structure array. If field `Type` is:

- `sigmoid`, then `ScoreTransform` has these fields:
 - `Slope` — The value of A in the sigmoid function
 - `Intercept` — The value of B in the sigmoid function
- `step`, then `ScoreTransform` has these fields:
 - `PositiveClassProbability`: the value of π in the step function. π represents:
 - The probability that an observation is in the positive class.
 - The posterior probability that a score is in the interval `(LowerBound,UpperBound)`.
 - `LowerBound`: the value $\max_{y_n=-1} s_n$ in the step function. It represents the lower bound of the interval that assigns the posterior probability of being in the positive class `PositiveClassProbability` to scores. Any observation with a score less than `LowerBound` has posterior probability of being the positive class `0`.
 - `UpperBound`: the value $\min_{y_n=+1} s_n$ in the step function. It represents the upper bound of the interval that assigns the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has posterior probability of being the positive class `1`.
- `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always `1`.

Definitions

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the output argument `ScoreTransform.Type` is `sigmoid`, then parameters A and B correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s_j < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- s_j the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the output argument `ScoreTransform.Type` is `step`, then the quantities $\max_{y_k=-1} s_k$

and $\min_{y_k=+1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Tips

Here is one way to predict positive class posterior probabilities.

- 1 Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as, `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.
- 2 Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, for example, `ScoreSVMModel`, is the same, trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- 3 Pass the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) and predictor data matrix to `predict`. The second column of the second output argument stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

Algorithms

If you reestimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to 'none' before estimating the new one

Introduced in R2014a

fitted

Class: GeneralizedLinearMixedModel

Fitted responses from generalized linear mixed-effects model

Syntax

```
mufit = fitted(glme)
mufit = fitted(glme, Name, Value)
```

Description

`mufit = fitted(glme)` returns the fitted conditional response of the generalized linear mixed-effects model `glme`.

`mufit = fitted(glme, Name, Value)` returns the fitted response with additional options specified by one or more name-value pair arguments. For example, you can specify to compute the marginal fitted response.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Conditional' — Indicator for conditional response

true (default) | false

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

Value	Description
true	Contributions from both fixed effects and random effects (conditional)
false	Contribution from only fixed effects (marginal)

To obtain fitted marginal response values, `fitted` computes the conditional mean of the response with the empirical Bayes predictor vector of random effects b set equal to 0. For more information, see “Conditional and Marginal Response” on page 29-2636

Example: 'Conditional',false

Output Arguments

mufit — Fitted response values

n -by-1 vector

Fitted response values, returned as an n -by-1 vector, where n is the number of observations.

Examples

Plot Observed Versus Fitted Values

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'mfr.mat'));
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\text{log}(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i$$

where

- `defectsij` is the number of defects observed in the batch produced by factory *i* during batch *j*.
- `μij` is the mean number of defects corresponding to factory *i* (where *i* = 1, 2, ..., 20) during batch *j* (where *j* = 1, 2, ..., 5).
- `newprocessij`, `time_devij`, and `temp_devij` are the measurements for each variable that correspond to factory *i* during batch *j*. For example, `newprocessij` indicates whether the batch produced by factory *i* during batch *j* used the new process.

- `supplier_Cij` and `supplier_Bij` are dummy variables that use effects (sum-to-zero) coding to indicate whether company **C** or **B**, respectively, supplied the process chemicals for the batch produced by factory *i* during batch *j*.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory *i* that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)  
'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects')
```

Generate the fitted conditional mean values for the model.

```
mufit = fitted(glme);
```

Create a scatterplot of the observed values versus fitted values.

```
figure  
scatter(mfr.defects, mufit)  
title('Residuals versus Fitted Values')  
xlabel('Fitted Values')  
ylabel('Residuals')
```

Definitions

Conditional and Marginal Response

A *conditional response* includes contributions from both fixed- and random-effects predictors. A *marginal response* includes contribution from only fixed effects.

Suppose the generalized linear mixed-effects model `glme` has an n -by- p fixed-effects design matrix X and an n -by- q random-effects design matrix Z . Also, suppose the

estimated p -by-1 fixed-effects vector is $\hat{\beta}$, and the q -by-1 empirical Bayes predictor vector of random effects is \hat{b} .

The fitted conditional response corresponds to the 'Conditional', true name-value pair argument, and is defined as

$$\hat{\mu}_{cond} = g^{-1}(\hat{\eta}_{ME}),$$

where $\hat{\eta}_{ME}$ is the linear predictor including the fixed- and random-effects of the generalized linear mixed-effects model

$$\hat{\eta}_{ME} = X\hat{\beta} + Z\hat{b} + \delta.$$

The fitted marginal response corresponds to the 'Conditional', false name-value pair argument, and is defined as

$$\hat{\mu}_{mar} = g^{-1}(\hat{\eta}_{FE}),$$

where $\hat{\eta}_{FE}$ is the linear predictor including only the fixed-effects portion of the generalized linear mixed-effects model

$$\hat{\eta}_{FE} = X\hat{\beta} + \delta.$$

fitted

Class: LinearMixedModel

Fitted responses from a linear mixed-effects model

Syntax

```
yfit = fitted(lme)
yfit = fitted(lme, Name, Value)
```

Description

`yfit = fitted(lme)` returns the fitted conditional response from the linear mixed-effects model `lme`.

`yfit = fitted(lme, Name, Value)` returns the fitted response from the linear mixed-effects model `lme` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify if you want to compute the fitted marginal response.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Conditional' — Indicator for conditional response

True (default) | False

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and either of the following.

True	Contribution from both fixed effects and random effects (conditional)
False	Contribution from only fixed effects (marginal)

Example: 'Conditional, 'False'

Output Arguments

yfit — Fitted response values*n*-by-1 vector

Fitted response values, returned as an *n*-by-1 vector, where *n* is the number of observations.

Examples

Compute Fitted Conditional and Marginal Responses

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10, 'NewDataVarName', 'FluRate', 'IndVarName', 'Region');
```

```
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by `Date`.

`Region` is a categorical variable. You can specify the contrasts for categorical variables using the `DummyVarCoding` name-value pair argument when fitting the model. When you do not specify the contrasts, `fitlme` uses the 'reference' contrast by default. Because the model has an intercept, `fitlme` takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example, $I[\text{MidAtl}]_i$ is the dummy variable representing the region `MidAtl`. For details, see “Dummy Indicator Variables”.

The corresponding model is

$$y_{im} = \beta_0 + \beta_1 I[\text{MidAtl}]_i + \beta_2 I[\text{ENCentral}]_i + \beta_3 I[\text{WNCentral}]_i + \beta_4 I[\text{SAtl}]_i + \beta_5 I[\text{ESCentral}]_i + \beta_6 I[\text{WSCentral}]_i + \beta_7 I[\text{Mtn}]_i + \beta_8 I[\text{Pac}]_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, β_j , $j = 0, 1, \dots, 8$, are the fixed-effects coefficients, with β_0 being the coefficient for region NE. b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i . The random effect has the prior distribution, $b_{0m} \sim N(0, \sigma_b^2)$ and the error term has the distribution, $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
lme = fitlme(flu2, 'FluRate ~ 1 + Region + (1|Date)')
```

```

'(Intercept)'	'(Intercept)'	'std'	0.6443	0.5297

Upper
0.78368

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.26627	0.24878	0.285

The *P*-values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term, σ_b , do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The conditional fitted response from the model at a given observation includes contributions from fixed and random effects. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week `10/9/2005` is

$$\begin{aligned}\hat{y}_{\text{WNCentral},10/9/2005} &= \hat{\beta}_0 + \hat{\beta}_3 I[\text{WNCentral}] + \hat{b}_{10/9/2005} \\ &= 1.2233 + 0.23687 - 0.1718 \\ &= 1.28837.\end{aligned}$$

This is the fitted conditional response, since it includes contributions to the estimate from both the fixed and random effects. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')
```

```
y_hat =
    1.2884
```

In the previous calculation, `beta(1)` corresponds to the estimate for β_0 and `beta(4)` corresponds to the estimate for β_3 . You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans =
    1.2884
```

The estimated marginal response for region `WNCentral` in week `10/9/2005` is

$$\begin{aligned}\hat{y}_{\text{WNCentral},10/9/2005}^{(\text{marginal})} &= \hat{\beta}_0 + \hat{\beta}_3 I[\text{WNCentral}] \\ &= 1.2233 + 0.23687 \\ &= 1.46017.\end{aligned}$$

Compute the fitted marginal response.

```
F = fitted(lme, 'Conditional', false);  
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans =
```

```
1.4602
```

Plot Residuals vs. Fitted Values

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);  
tbl.Subject = nominal(tbl.Subject);  
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```
F = fitted(lme);  
R = residuals(lme);
```

Plot the residuals versus the fitted values.

```
plot(F, R, 'bx')  
xlabel('Fitted Values')  
ylabel('Residuals')
```

Now, plot the residuals versus the fitted values, grouped by program.

```
figure()  
gscatter(F,R,Program)
```

Definitions

Fitted Conditional and Marginal Response

A conditional response includes contributions from both fixed and random effects, whereas a marginal response includes contribution from only fixed effects.

Suppose the linear mixed-effects model, lme , has an n -by- p fixed-effects design matrix X and an n -by- q random-effects design matrix Z . Also, suppose the p -by-1 estimated

fixed-effects vector is $\hat{\beta}$, and the q -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is \hat{b} . The fitted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

and the fitted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta},$$

fixedEffects

Class: GeneralizedLinearMixedModel

Estimates of fixed effects and related statistics

Syntax

```
beta = fixedEffects(glme)
[beta,betaname] = fixedEffects(glme)
[beta,betaname,stats] = fixedEffects(glme)
[ ___ ] = fixedEffects(glme,Name,Value)
```

Description

`beta = fixedEffects(glme)` returns the estimated fixed-effects coefficients, **beta**, of the generalized linear mixed-effects model **glme**.

`[beta,betaname] = fixedEffects(glme)` also returns the names of estimated fixed-effects coefficients in **betaname**. Each name corresponds to a fixed-effects coefficient in **beta**.

`[beta,betaname,stats] = fixedEffects(glme)` also returns a table of statistics, **stats**, related to the estimated fixed-effects coefficients of **glme**.

`[___] = fixedEffects(glme,Name,Value)` returns any of the output arguments in previous syntaxes using additional options specified by one or more **Name,Value** pair arguments. For example, you can specify the confidence level, or the method for computing the approximate degrees of freedom for the *t*-statistic.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a **GeneralizedLinearMixedModel** object. For properties and methods of this object, see **GeneralizedLinearMixedModel**.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range [0,1]

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha', 0.01

Data Types: single | double

'DFMethod' — Method for computing approximate degrees of freedom

'residual' (default) | 'none'

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

Value	Description
'residual'	The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
'none'	All degrees of freedom are set to infinity.

Example: 'DFMethod', 'none'

Output Arguments

beta — Estimated fixed-effects coefficients

vector

Estimated fixed-effects coefficients of the fitted generalized linear mixed-effects model `glme`, returned as a vector.

betanames — Names of fixed-effects coefficients

table

Names of fixed-effects coefficients in `beta`, returned as a table.

stats — Fixed-effects estimates and related statistics

dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Column Name	Description
Name	Name of the fixed-effects coefficient
Estimate	Estimated coefficient value
SE	Standard error of the estimate
tStat	<i>t</i> -statistic for a test that the coefficient is 0
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic
Lower	Lower limit of a 95% confidence interval for the fixed-effects coefficient
Upper	Upper limit of a 95% confidence interval for the fixed-effects coefficient

When fitting a model using `fitglme` and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), if you specify the 'CovarianceMethod' name-value pair argument as 'conditional', then SE does not account for the uncertainty in estimating the covariance parameters. To account for this uncertainty, specify 'CovarianceMethod' as 'JointHessian'.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REMP'), `fixedEffects` bases the fixed effects estimates and related statistics on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Examples

Estimate Fixed-Effects Coefficients

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'mfr.mat'));
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company **C** or **B**, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
                'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects')
```

Compute and display the estimated fixed-effects coefficient values and related statistics.

```
[beta, betanames, stats] = fixedEffects(glme);
stats
```

```
stats =
```

```
FIXED EFFECT COEFFICIENTS: DFMETHOD = 'RESIDUAL', ALPHA = 0.05
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	1.4689	0.15988	9.1875	94	9.8194e-15
'newprocess'	-0.36766	0.17755	-2.0708	94	0.041122
'time_dev'	-0.094521	0.82849	-0.11409	94	0.90941
'temp_dev'	-0.28317	0.9617	-0.29444	94	0.76907
'supplier_C'	-0.071868	0.078024	-0.9211	94	0.35936

'supplier_B'	0.071072	0.07739	0.91836	94	0.36078
Lower		Upper			
1.1515		1.7864			
-0.72019		-0.015134			
-1.7395		1.5505			
-2.1926		1.6263			
-0.22679		0.083051			
-0.082588		0.22473			

The returned results indicate, for example, that the estimated coefficient for `temp_dev` is -0.28317 . Its large *P*-value, 0.76907 , indicates that it is not a statistically significant predictor at the 5% significance level. Additionally, the confidence interval boundaries `Lower` and `Upper` indicate that the 95% confidence interval for the coefficient for `temp_dev` is $[-2.1926, 1.6263]$. This interval contains 0, which supports the conclusion that `temp_dev` is not statistically significant at the 5% significance level.

fixedEffects

Class: LinearMixedModel

Estimates of fixed effects and related statistics

Syntax

```
beta = fixedEffects(lme)
[beta,betaname] = fixedEffects(lme)
[beta,betaname,stats] = fixedEffects(lme)
[beta,betaname,stats] = fixedEffects(lme,Name,Value)
```

Description

`beta = fixedEffects(lme)` returns the estimated fixed-effects coefficients, `beta`, of the linear mixed-effects model `lme`.

`[beta,betaname] = fixedEffects(lme)` also returns the names of estimated fixed-effects coefficients in `betaname`. Each name corresponds to a fixed-effects coefficient in `beta`.

`[beta,betaname,stats] = fixedEffects(lme)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics in `stats`.

`[beta,betaname,stats] = fixedEffects(lme,Name,Value)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

'DFMethod' — Method for computing approximate degrees of freedom

'residual' (default) | 'satterthwaite' | 'none'

Method for computing approximate degrees of freedom for the t -statistic that tests the fixed-effects coefficients against 0, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'residual'

Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.

'satterthwaite'

Satterthwaite approximation.

'none'

All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod', 'satterthwaite'

Output Arguments

beta — Fixed-effects coefficients estimates

vector

Fixed-effects coefficients estimates of the fitted linear mixed-effects model `lme`, returned as a vector.

betanames — Names of fixed-effects coefficients

table

Names of fixed-effects coefficients in `beta`, returned as a table.

stats — Fixed-effects estimates and related statistics

dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Name	Name of the fixed effect coefficient
Estimate	Estimated coefficient value
SE	Standard error of the estimate
tStat	<i>t</i> -statistic for a test that the coefficient is zero
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic
Lower	Lower limit of a 95% confidence interval for the fixed-effect coefficient
Upper	Upper limit of a 95% confidence interval for the fixed-effect coefficient

Examples

Display Fixed-Effects Coefficient Estimates and Names

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

The data set `weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between week and program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Display the fixed-effects coefficient estimates and corresponding fixed-effects names.

```

```
'Program_D:Week'
```

Compute Coefficient Estimates and Related Statistics

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the fixed-effects coefficients estimates and related statistics.

```
[~,~,stats] = fixedEffects(lme)
```

```
stats =
```

```
FIXED EFFECT COEFFICIENTS: DFMETHOD = 'RESIDUAL', ALPHA = 0.05
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	50.133	2.2652	22.132	389	7.7727e-71
'Acceleration'	-0.58327	0.13394	-4.3545	389	1.7075e-05
'Horsepower'	-0.16954	0.0072609	-23.35	389	5.188e-76

Lower	Upper
45.679	54.586
-0.84661	-0.31992
-0.18382	-0.15527

The small P -values (under pValue) indicate that all fixed-effects coefficients are significant.

Compute Confidence Intervals with Specified Options

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'));
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Compute the 99% confidence intervals for fixed-effects coefficients, using the residual method to compute the degrees of freedom. This is the default method.

```
[~,~,stats] = fixedEffects(lme, 'alpha', 0.01)
```

```
stats =
```

```
FIXED EFFECT COEFFICIENTS: DFMETHOD = 'RESIDUAL', ALPHA = 0.01
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	3.1196	0.88681	3.5178	12	0.0042407
'Shift_Morning'	-0.3868	0.48344	-0.80009	12	0.43921
'Shift_Night'	1.9856	0.48344	4.1072	12	0.0014535

Lower	Upper
0.41081	5.8284
-1.8635	1.0899
0.5089	3.4623

Compute the 99% confidence intervals for fixed-effects coefficients, using the Satterthwaite approximation to compute the degrees of freedom.

```
[~,~,stats] = fixedEffects(lme, 'DFMethod', 'satterthwaite', 'alpha', 0.01)
```

```
stats =
```

```
FIXED EFFECT COEFFICIENTS: DFMETHOD = 'SATTERTHWAITE', ALPHA = 0.01
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	3.1196	0.88681	3.5178	6.123	0.01214
'Shift_Morning'	-0.3868	0.48344	-0.80009	10	0.44225
'Shift_Night'	1.9856	0.48344	4.1072	10	0.00212

Lower	Upper
-0.14122	6.3804
-1.919	1.1454
0.45343	3.5178

The Satterthwaite approximation usually produces smaller DF values than the residual method. That is why it produces larger P -values (`pValue`) and larger confidence intervals (see `Lower` and `Upper`).

`coefCI` | `coefTest` | `fitlme` | `LinearMixedModel` | `randomEffects`

fpdf

F probability density function

Syntax

$Y = \text{fpdf}(X, V1, V2)$

Description

$Y = \text{fpdf}(X, V1, V2)$ computes the F pdf at each of the values in X using the corresponding numerator degrees of freedom $V1$ and denominator degrees of freedom $V2$. X , $V1$, and $V2$ can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. $V1$ and $V2$ parameters must contain real positive values, and the values in X must lie on the interval $[0 \infty)$.

The probability density function for the F distribution is

$$y = f(x | v_1, v_2) = \frac{\Gamma\left(\frac{v_1 + v_2}{2}\right)}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} \frac{x^{\frac{v_1-2}{2}}}{\left[1 + \left(\frac{v_1}{v_2}\right)x\right]^{\frac{v_1+v_2}{2}}}$$

Examples

```
y = fpdf(1:6,2,2)
y =
    0.2500    0.1111    0.0625    0.0400    0.0278    0.0204

z = fpdf(3,5:10,5:10)
z =
    0.0689    0.0659    0.0620    0.0577    0.0532    0.0487

fracfact

Fractional factorial design

Syntax

```
X = fracfact(gen)
[X,conf] = fracfact(gen)
[X,conf] = fracfact(gen,Name,Value)
```

Description

`X = fracfact(gen)` creates the two-level fractional factorial design defined by the generator `gen`.

`[X,conf] = fracfact(gen)` returns a cell array of character vectors containing the confounding pattern for the design.

`[X,conf] = fracfact(gen,Name,Value)` creates a fractional factorial designs with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

gen

Either a cell array of character vectors where each cell contains one “word,” or a character array consisting of “words” separated by spaces. “Words” consist of case-sensitive letters or groups of letters, where 'a' represents value 1, 'b' represents value 2, ..., 'A' represents value 27, ..., 'Z' represents value 52.

Each word defines how the corresponding factor's levels are defined as products of generators from a 2^K full-factorial design. K is the number of letters of the alphabet in `gen`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

'FactorNames'

Cell array specifying the name for each factor.

Default: {'X1', 'X2', ...}

'MaxInt'

Positive integer setting the maximum level of interaction to include in the confounding output.

Default: 2

Output Arguments

X

The two-level fractional factorial design. X is a matrix of size N-by-P, where

- $N = 2^K$, where K is the number of letters of the alphabet in **gen**.
- P is the number of words in **gen**.

Because X is a two-level design, the components of X are ± 1 . For the meaning of X, see “Fractional Factorial Designs” on page 24-5.

conf

Cell array of character vectors containing the confounding pattern for the design.

Examples

Generate a fractional factorial design for four variables, where the fourth variable is the product of the first three:

```
x = fracfact('a b c abc')
```

```
x =  
  -1  -1  -1  -1  
  -1  -1   1   1  
  -1   1  -1   1  
  -1   1   1  -1  
   1  -1  -1   1  
   1  -1   1  -1  
   1   1  -1  -1  
   1   1   1   1
```

Find generators for a six-factor design that uses four factors and achieves resolution IV using `fracfactgen`. Use the result to specify the design:

```
generators = fracfactgen('a b c d e f',4, ... % 4 factors  
  4) % resolution 4
```

```
generators =  
  'a'  
  'b'  
  'c'  
  'd'  
  'bcd'  
  'acd'
```

```
x = fracfact(generators)
```

```
x =  
  -1  -1  -1  -1  -1  -1  
  -1  -1  -1   1   1   1  
  -1  -1   1  -1   1   1  
  -1  -1   1   1  -1  -1  
  -1   1  -1  -1   1  -1  
  -1   1  -1   1  -1   1  
  -1   1   1  -1  -1   1  
   1  -1  -1  -1  -1   1  
   1  -1  -1   1   1  -1  
   1  -1   1  -1   1  -1  
   1  -1   1   1  -1   1  
   1   1  -1  -1   1   1  
   1   1  -1   1  -1  -1  
   1   1   1  -1  -1  -1  
   1   1   1   1   1   1
```

fracfactgen

Fractional factorial design generators

Syntax

```
generators = fracfactgen(terms)
generators = fracfactgen(terms,k)
generators = fracfactgen(terms,k,R)
generators = fracfactgen(terms,k,R,basic)
```

Description

`generators = fracfactgen(terms)` uses the Franklin-Bailey algorithm to find generators for the smallest two-level fractional-factorial design for estimating linear model terms specified by `terms`. `terms` is a character vector consisting of words formed from the 52 case-sensitive letters a-Z, separated by spaces. Use 'a' - 'z' for the first 26 factors, and, if necessary, 'A' - 'Z' for the remaining factors. For example, `terms = 'a b c ab ac'`. Single-character words indicate main effects to be estimated; multiple-character words indicate interactions. Alternatively, `terms` is an m -by- n matrix of 0s and 1s where m is the number of model terms to be estimated and n is the number of factors. For example, if `terms` contains rows `[0 1 0 0]` and `[1 0 0 1]`, then the factor `b` and the interaction between factors `a` and `d` are included in the model. `generators` is a cell array of character vectors with one generator per cell. Pass `generators` to `fracfact` to produce the fractional-factorial design and corresponding confounding pattern.

`generators = fracfactgen(terms,k)` returns generators for a two-level fractional-factorial design with 2^k -runs, if possible. If `k` is `[]`, `fracfactgen` finds the smallest design.

`generators = fracfactgen(terms,k,R)` finds a design with resolution `R`, if possible. The default resolution is 3.

A design of *resolution R* is one in which no n -factor interaction is confounded with any other effect containing less than $R - n$ factors. Thus a resolution III design does not confound main effects with one another but may confound them with two-way interactions, while a resolution IV design does not confound either main effects or two-way interactions but may confound two-way interactions with each other.

If `fracfactgen` is unable to find a design at the requested resolution, it tries to find a lower-resolution design sufficient to calibrate the model. If it is successful, it returns the generators for the lower-resolution design along with a warning. If it fails, it returns an error.

`generators = fracfactgen(terms,k,R,basic)` also accepts a vector `basic` specifying the indices of factors that are to be treated as basic. These factors receive full-factorial treatments in the design. The default includes factors that are part of the highest-order interaction in `terms`.

Examples

Suppose you wish to determine the effects of four two-level factors, for which there may be two-way interactions. A full-factorial design would require $2^4 = 16$ runs. The `fracfactgen` function finds generators for a resolution IV (separating main effects) fractional-factorial design that requires only $2^3 = 8$ runs:

```
generators = fracfactgen('a b c d',3,4)
generators =
  'a'
  'b'
  'c'
  'abc'
```

The more economical design and the corresponding confounding pattern are returned by `fracfact`:

```
[dfF,confounding] = fracfact(generators)
dfF =
  -1  -1  -1  -1
  -1  -1   1   1
  -1   1  -1   1
  -1   1   1  -1
   1  -1  -1   1
   1  -1   1  -1
   1   1  -1  -1
   1   1   1   1
confounding =
  'Term'      'Generator'      'Confounding'
  'X1'        'a'              'X1'
  'X2'        'b'              'X2'
```

'X3'	'c'	'X3'
'X4'	'abc'	'X4'
'X1*X2'	'ab'	'X1*X2 + X3*X4'
'X1*X3'	'ac'	'X1*X3 + X2*X4'
'X1*X4'	'bc'	'X1*X4 + X2*X3'
'X2*X3'	'bc'	'X1*X4 + X2*X3'
'X2*X4'	'ac'	'X1*X3 + X2*X4'
'X3*X4'	'ab'	'X1*X2 + X3*X4'

The confounding pattern shows, for example, that the two-way interaction between X1 and X2 is confounded by the two-way interaction between X3 and X4.

Introduced in R2006a

friedman

Friedman's test

Syntax

```
p = friedman(x, reps)
p = friedman(x, reps, displayopt)
[p, tbl] = friedman( ___ )
[p, tbl, stats] = friedman( ___ )
```

Description

`p = friedman(x, reps)` returns the p -value for the nonparametric Friedman's test to compare column effects in a two-way layout. `friedman` tests the null hypothesis that the column effects are all the same against the alternative that they are not all the same.

`p = friedman(x, reps, displayopt)` enables the ANOVA table display when `displayopt` is 'on' (default) and suppresses the display when `displayopt` is 'off'.

`[p, tbl] = friedman(___)` returns the ANOVA table (including column and row labels) in cell array `tbl`.

`[p, tbl, stats] = friedman(___)` also returns a structure `stats` that you can use to perform a follow-up multiple comparison test.

Examples

Test For Column Effects Using Friedman's Test

This example shows how to test for column effects in a two-way layout using Friedman's test.

Load the sample data.

```
load popcorn
```

```
popcorn
```

```
popcorn =
```

```
  5.5000  4.5000  3.5000
  5.5000  4.5000  4.0000
  6.0000  4.0000  3.0000
  6.5000  5.0000  4.0000
  7.0000  5.5000  5.0000
  7.0000  5.0000  4.5000
```

This data comes from a study of popcorn brands and popper type (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper type (Oil and Air). The study popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Use Friedman's test to determine whether the popcorn brand affects the yield of popcorn.

```
p = friedman(popcorn,3)
```

```
p =
```

```
  0.0010
```

Friedman's ANOVA Table					
Source	SS	df	MS	Chi-sq	Prob>Chi-sq
Columns	99.75	2	49.875	13.76	0.001
Interaction	0.0833	2	0.0417		
Error	16.1667	12	1.3472		
Total	116	17			

Test for column effects after row effects are removed

The small value of $p = 0.001$ indicates the popcorn brand affects the yield of popcorn.

Input Arguments

x — Sample data
matrix

Sample data for the hypothesis test, specified as a matrix. The columns of **x** represent changes in a factor A. The rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input **reps** indicates the number of replicates in each “cell,” which must be constant.

Data Types: `single` | `double`

reps — Number of replicates per cell

1 (default) | positive integer value

Number of replicates per cell, specified as a positive integer value.

Data Types: `single` | `double`

displayopt — ANOVA table display option

'off' (default) | 'on'

ANOVA table display option, specified as 'off' or 'on'.

If `displayopt` is 'on', then `friedman` displays a figure showing an ANOVA table, which divides the variability of the ranks into two or three parts:

- The variability due to the differences among the column effects
- The variability due to the interaction between rows and columns (if `reps` is greater than its default value of 1)
- The remaining variability not explained by any systematic source

The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the p value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting **Copy Text** from the **Edit** menu.

Output Arguments

p — p -value

scalar value in the range [0, 1]

p -value of the test, returned as a scalar value in the range $[0, 1]$. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

tbl – ANOVA table

cell array

ANOVA table, including column and row labels, returned as a cell array. The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the p value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting **Copy Text** from the **Edit** menu.

stats – Test data

structure

Test data, returned as a structure. `friedman` evaluates the hypothesis that the column effects are all the same against the alternative that they are not all the same. However, sometimes it is preferable to perform a test to determine which pairs of column effects are significantly different, and which are not. You can use the `multcompare` function to perform such tests by supplying `stats` as the input value.

Definitions

Friedman's Test

Friedman's test is similar to classical balanced two-way ANOVA, but it tests only for column effects after adjusting for possible row effects. It does not test for row effects or interaction effects. Friedman's test is appropriate when columns represent treatments that are under study, and rows represent nuisance effects (blocks) that need to be taken into account but are not of any interest.

The different columns of X represent changes in a factor A. The different rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input `reps` indicates the number of replicates in each “cell,” which must be constant.

The matrix below illustrates the format for a set-up where column factor A has three levels, row factor B has two levels, and there are two replicates (`reps=2`). The subscripts indicate row, column, and replicate, respectively.

$$\begin{bmatrix} x_{111} & x_{121} & x_{131} \\ x_{112} & x_{122} & x_{132} \\ x_{211} & x_{221} & x_{231} \\ x_{212} & x_{222} & x_{232} \end{bmatrix}$$

Friedman's test assumes a model of the form

$$x_{ijk} = \mu + \alpha_i + \beta_j + \varepsilon_{ijk}$$

where μ is an overall location parameter, α_i represents the column effect, β_j represents the row effect, and ε_{ijk} represents the error. This test ranks the data within each level of B, and tests for a difference across levels of A. The `p` that `friedman` returns is the p value for the null hypothesis that $\alpha_i = 0$. If the p value is near zero, this casts doubt on the null hypothesis. A sufficiently small p value suggests that at least one column-sample median is significantly different than the others; i.e., there is a main effect due to factor A. The choice of a critical p value to determine whether a result is “statistically significant” is left to the researcher. It is common to declare a result significant if the p value is less than 0.05 or 0.01.

Friedman's test makes the following assumptions about the data in X :

- All data come from populations having the same continuous distribution, apart from possibly different locations due to column and row effects.
- All observations are mutually independent.

The classical two-way ANOVA replaces the first assumption with the stronger assumption that data come from normal distributions.

frnd

F random numbers

Syntax

```
R = frnd(V1,V2)
R = frnd(V1,V2,m,n,...)
R = frnd(V1,V2,[m,n,...])
```

Description

`R = frnd(V1,V2)` generates random numbers from the *F* distribution with numerator degrees of freedom *V1* and denominator degrees of freedom *V2*. *V1* and *V2* can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for *V1* or *V2* is expanded to a constant array with the same dimensions as the other input.

`R = frnd(V1,V2,m,n,...)` or `R = frnd(V1,V2,[m,n,...])` generates an *m*-by-*n*-by-... array containing random numbers from the *F* distribution with parameters *V1* and *V2*. *V1* and *V2* can each be scalars or arrays of the same size as *R*.

Examples

```
n1 = frnd(1:6,1:6)
n1 =
    0.0022    0.3121    3.0528    0.3189    0.2715    0.9539
```

```
n2 = frnd(2,2,[2 3])
n2 =
    0.3186    0.9727    3.0268
    0.2052   148.5816    0.2191
```

```
n3 = frnd([1 2 3;4 5 6],1,2,3)
n3 =
    0.6233    0.2322   31.5458
    2.5848    0.2121    4.4955
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

fscnca

Feature selection using neighborhood component analysis for classification

Syntax

```
mdl = fscnca(X,Y)
mdl = fscnca(X,Y,Name,Value)
```

Description

`mdl = fscnca(X,Y)` performs feature selection for classification using the predictors in `X` and responses in `Y`.

`fscnca` learns the feature weights by using a diagonal adaptation of neighborhood component analysis (NCA) with regularization.

`mdl = fscnca(X,Y,Name,Value)` performs feature selection for classification with additional options specified by one or more name-value pair arguments.

Examples

Detect Relevant Features in Data Using NCA for Classification

Generate toy data where the response variable depends on the 3rd, 9th, and 15th predictors.

```
rng(0,'twister'); % For reproducibility
N = 100;
X = rand(N,20);
y = -ones(N,1);
y(X(:,3).*X(:,9)./X(:,15) < 0.4) = 1;
```

Fit the neighborhood component analysis model for classification.

```
mdl = fscnca(X,y,'Solver','sgd','Verbose',1);
```

Relative two norm of the final step = 6.588e-02, TolX = 1.000e-06
EXIT: Iteration or pass limit reached.

Plot the selected features. The weights of the irrelevant features should be close to zero.

figure()

```
plot mdl.FeatureWeights, 'ro'  
grid on  
xlabel('Feature index')  
ylabel('Feature weight')
```

fscnca correctly detects the relevant features.

Identify Relevant Features for Classification

Load sample data

```
load ovariancancer;  
whos
```

Name	Size	Bytes	Class	Attributes
grp	216x1	26784	cell	
obs	216x4000	3456000	single	

This example uses the high-resolution ovarian cancer data set that was generated using the WCX2 protein array. The data is from the FDA-NCI Clinical Proteomics Program Databank. After some preprocessing steps, the data set has two variables: `obs` and `grp`. The `obs` variable consists 216 observations with 4000 features. Each element in `grp` defines the group to which the corresponding row of `obs` belongs.

Divide data into training and test sets

Use `cvpartition` to divide data into a training set of size 160 and a test set of size 56. Both the training set and the test set have roughly the same group proportions as in `grp`.

```
rng(1); % For reproducibility
cvp = cvpartition(grp, 'holdout', 56)
Xtrain = obs(cvp.training, :);
ytrain = grp(cvp.training, :);
Xtest = obs(cvp.test, :);
ytest = grp(cvp.test, :);
```

```
ans =
```

```
Hold-out cross validation partition
  NumObservations: 216
    NumTestSets: 1
      TrainSize: 160
      TestSize: 56
```

Determine if feature selection is necessary

Compute generalization error without fitting.

```
nca = fscnca(Xtrain, ytrain, 'FitMethod', 'none');
L = loss(nca, Xtest, ytest)
```

```
L =
```

```
0.0893
```

This option computes the generalization error of the neighborhood component analysis (NCA) feature selection model using the initial feature weights (in this case the default feature weights) provided in `fscnca`.

Fit NCA without regularization parameter ($\text{Lambda} = 0$)

```
nca = fscnca(Xtrain,ytrain,'FitMethod','exact','Lambda',0,...  
            'Solver','sgd','Standardize',true);  
L = loss(nca,Xtest,ytest)
```

```
L =
```

```
    0.0714
```

The improvement on the loss value suggests that feature selection is a good idea. Tuning the λ value usually improves the results.

Tune the regularization parameter for NCA using five-fold cross-validation

Tuning λ means finding the λ value that produces produce the minimum classification loss. To tune λ using cross-validation:

1. Partition the training data into five folds and extract the number of validation (test) sets. For each fold, `cvpartition` assigns four-fifths of the data as a training set, and one-fifth of the data as a test set.

```
cvp = cvpartition(ytrain,'kfold',5);  
numvalidsets = cvp.NumTestSets;
```

Assign λ values and create an array to store the loss function values.

```
n = length(ytrain);  
lambdaval = linspace(0,20,20)/n;  
lossvals = zeros(length(lambdaval),numvalidsets);
```

2. Train the NCA model for each λ value, using the training set in each fold.
3. Compute the classification loss for the corresponding test set in the fold using the NCA model. Record the loss value.

4. Repeat this process for all folds and all λ values.

```

for i = 1:length(lambdaval)
    for k = 1:numvalidsets
        X = Xtrain(cvp.training(k),:);
        y = ytrain(cvp.training(k),:);
        Xvalid = Xtrain(cvp.test(k),:);
        yvalid = ytrain(cvp.test(k),:);

        nca = fscnca(X,y,'FitMethod','exact', ...
                    'Solver','sgd','Lambda',lambdaval(i), ...
                    'IterationLimit',30,'GradientTolerance',1e-4, ...
                    'Standardize',true);

        lossvals(i,k) = loss(nca,Xvalid,yvalid,'LossFunction','classiferror');
    end
end

```

Compute the average loss obtained from the folds for each λ value.

```
meanloss = mean(lossvals,2);
```

Plot the average loss values versus the λ values.

```

figure()
plot(lambdaval,meanloss,'ro-')
xlabel('Lambda')
ylabel('Loss (MSE)')
grid on

- “Tune Regularization Parameter to Detect Features Using NCA for Classification”

Input Arguments

X — Predictor variable values

n -by- p matrix

Predictor variable values, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables.

Data Types: `single` | `double`

Y — Class labels

categorical vector | logical vector | numeric vector | cell array of character vectors of length n | character matrix with n rows

Class labels, specified as a categorical vector, logical vector, numeric vector, cell array of character vectors of length n , or character matrix with n rows, where n is the number of observations. Element i or row i of Y is the class label corresponding to row i of X (observation i).

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Solver', 'sgd', 'Weights', W, 'Lambda', 0.0003` specifies the solver as the stochastic gradient descent, the observation weights as the values in the vector `W`, and sets the regularization parameter at 0.0003.

Fitting Options

'FitMethod' — Method for fitting the model

`'exact'` (default) | `'none'` | `'average'`

Method for fitting the model, specified as the comma-separated pair consisting of `'FitMethod'` and one of the following:

- `'exact'` — Performs fitting using all of the data.

- `'none'` — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fscnc`.
- `'average'` — Divides the data into partitions (subsets), fits each partition using the `exact` method, and returns the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Example: `'FitMethod','none'`

Data Types: `char`

'NumPartitions' — Number of partitions

`max(2,min(10,n))` (default) | integer between 2 and n

Number of partitions to split the data for using with `'FitMethod','average'` option, specified as the comma-separated pair consisting of `'NumPartitions'` and an integer value between 2 and n , where n is the number of observations.

Example: `'NumPartitions',15`

Data Types: `double` | `single`

'Lambda' — Regularization parameter

$1/n$ (default) | nonnegative scalar

Regularization parameter, specified as the comma-separated pair consisting of `'Lambda'` and a nonnegative scalar.

For n observations, the best `Lambda` value that minimizes the generalization error of the NCA model is expected to be a multiple of $1/n$.

Example: `'Lambda',0.002`

Data Types: `double` | `single`

'LengthScale' — Width of the kernel

1 (default) | positive real scalar

Width of the kernel, specified as the comma-separated pair consisting of `'LengthScale'` and a positive real scalar.

A length scale value of 1 is sensible when all predictors are on the same scale. If the predictors in X are of very different magnitudes, then consider standardizing the predictor values using `'Standardize',true` and setting `'LengthScale',1`.

Example: `'LengthScale',1.5`

Data Types: `double` | `single`

'InitialFeatureWeights' — Initial feature weights

`ones(p,1)` (default) | p -by-1 vector of real positive scalars

Initial feature weights, specified as the comma-separated pair consisting of 'InitialFeatureWeights' and a p -by-1 vector of real positive scalars, where p is the number of predictors in the training data.

The regularized objective function for optimizing feature weights is nonconvex. As a result, using different initial feature weights can give different results. Setting all initial feature weights to 1 generally works well, but in some cases, random initialization using `rand(p,1)` can give better quality solutions.

Data Types: `double` | `single`

'Weights' — Observation weights

n -by-1 vector of 1s (default) | n -by-1 vector of real positive scalars

Observation weights, specified as the comma-separated pair consisting of 'ObservationWeights' and an n -by-1 vector of real positive scalars. Use observation weights to specify higher importance of some observations compared to others. The default weights assign equal importance to all observations.

Data Types: `double` | `single`

'Prior' — Prior probabilities for each class

'empirical' (default) | 'uniform' | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following:

- 'empirical' — fscnca obtains the prior class probabilities from class frequencies.
- 'uniform' — fscnca sets all class probabilities equal.
- Structure with two fields:
 - `ClassProbs` — Vector of class probabilities. If these are numeric values with a total greater than 1, fscnca normalizes them to add up to 1.
 - `ClassNames` — Class names corresponding to the class probabilities in `ClassProbs`.

Example: 'Prior', 'uniform'

Data Types: `char` | `struct`

'Standardize' — Indicator for standardizing predictor data

0 (default) | 1

Indicator for standardizing the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and either 0 (`false`) or 1 (`true`). For more information, see “Impact of Standardization” on page 15-131.

Example: `'Standardize',1`

Data Types: `logical`

'Verbose' — Verbosity level indicator

0 (default) | 1 | >1

Verbosity level indicator for the convergence summary display, specified as the comma-separated pair consisting of `'Verbose'` and one of the following:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function values
- > 1 — More convergence information, depending on the fitting algorithm

When using `'minibatch-lbfgs'` solver and verbosity level > 1, the convergence information includes iteration the log from intermediate mini-batch LBFGS fits.

Example: `'Verbose',1`

Data Types: `double` | `single`

'Solver' — Solver type

`'lbfgs'` | `'sgd'` | `'minibatch-lbfgs'`

Solver type for estimating feature weights, specified as the comma-separated pair consisting of `'Solver'` and one of the following:

- `'lbfgs'` — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- `'sgd'` — Stochastic gradient descent (SGD) algorithm
- `'minibatch-lbfgs'` — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Default is `'lbfgs'` for $n \leq 1000$, and `'sgd'` for $n > 1000$.

Example: `'solver','minibatch-lbfgs'`

Data Types: char

'LossFunction' — Loss function

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFunction' and one of the following.

- 'classiferror' — Misclassification error, defined as

$$\frac{1}{n} \sum_{i=1}^n I(k_i \neq t_i),$$

where k_i is the predicted class and t_i is the true class for observation i . $I(k_i \neq t_i)$ is the indicator for when the k_i is not the same as t_i .

- Function handle — Custom loss function. For example, for the 'LossFunction', L name-value pair, L must have the following form:

`L = lossFcn(Yn, Ym)`

`Yn` is an n -by-1 vector and `Ym` is an m -by-1 vector. `L` is an n -by- m matrix of loss values such that `L(i, j)` is the loss value for `Yn(i)` and `Ym(j)`.

Example: 'LossFunction', L

Data Types: char | function_handle

'CacheSize' — Memory size

1000MB (default) | integer

Memory size, in MB, to use for objective function and gradient computation, specified as the comma-separated pair consisting of 'CacheSize' and an integer.

Example: 'CacheSize', 1500MB

Data Types: double | single

LBFGS Options

'HessianHistorySize' — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of history buffer for Hessian approximation for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. At each iteration the function uses the most recent HessianHistorySize iterations to build an approximation to the inverse Hessian.

Example: 'HessianHistorySize',20

Data Types: double | single

'InitialStepSize' — Initial step size

'auto' (default) | positive real scalar

Initial step size for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'InitialStepSize' and a positive real scalar. By default, the function determines the initial step size automatically.

Data Types: double | single

'LineSearchMethod' — Line search method

'weakwolfe' (default) | 'strongwolfe' | 'backtracking'

Line search method, specified as the comma-separated pair consisting of 'LineSearchMethod' and one of the following:

- 'weakwolfe' — Weak Wolfe line search
- 'strongwolfe' — Strong Wolfe line search
- 'backtracking' — Backtracking line search

Example: 'LineSearchMethod','backtracking'

Data Types: char

'MaxLineSearchIterations' — Maximum number of line search iterations

20 (default) | positive integer

Maximum number of line search iterations, specified as the comma-separated pair consisting of 'MaxLineSearchIterations' and a positive integer.

Example: 'MaxLineSearchIterations',25

Data Types: double | single

'GradientTolerance' — Relative convergence tolerance

1e-6 (default) | positive real scalar

Relative convergence tolerance on the gradient norm for solver `lbfgs`, specified as the comma-separated pair consisting of `'GradientTolerance'` and a positive real scalar.

Example: `'GradientTolerance',0.000002`

Data Types: `double` | `single`

SGD Options

'InitialLearningRate' — Initial learning rate for `'sgd'` solver

`'auto'` (default) | positive real scalar

Initial learning rate for the `'sgd'` solver, specified as the comma-separated pair consisting of `'InitialLearningRate'` and a positive real scalar.

When using solver type `'sgd'`, the learning rate decays over iterations starting with the value specified for `'InitialLearningRate'`.

The default `'auto'` means that the initial learning rate is determined using experiments on small subsets of data. Use the `NumTuningIterations` name-value pair argument to specify the number of iterations for automatically tuning the initial learning rate. Use the `TuningSubsetSize` name-value pair argument to specify the number of observations to use for automatically tuning the initial learning rate.

For solver type `'minibatch-lbfgs'`, you can set `'InitialLearningRate'` to a very high value. In this case, the function applies LBFGS to each mini-batch separately with initial feature weights from the previous mini-batch.

To make sure the chosen initial learning rate decreases the objective value with each iteration, plot the `Iteration` versus the `Objective` values saved in the `mdl.FitInfo` property.

You can use the `refit` method with `'InitialFeatureWeights'` equal to `mdl.FeatureWeights` to start from the current solution and run additional iterations

Example: `'InitialLearningRate',0.9`

Data Types: `double` | `single`

'MiniBatchSize' — Number of observations to use in each batch for the `'sgd'` solver

`min(10,n)` (default) | positive integer value from 1 to *n*

Number of observations to use in each batch for the 'sgd' solver, specified as the comma-separated pair consisting of 'MiniBatchSize' and a positive integer from 1 to n .

Example: 'MiniBatchSize',25

Data Types: double | single

'PassLimit' — Maximum number of passes for solver 'sgd'

5 (default) | positive integer

Maximum number of passes through all n observations for solver 'sgd', specified as the comma-separated pair consisting of 'PassLimit' and a positive integer. Each pass through all of the data is called an epoch.

Example: 'PassLimit',10

Data Types: double | single

'NumPrint' — Frequency of batches for displaying convergence summary

10 (default) | positive integer value

Frequency of batches for displaying convergence summary for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumPrint' and a positive integer. This argument applies when the 'Verbose' value is greater than 0. NumPrint mini-batches are processed for each line of the convergence summary that is displayed on the command line.

Example: 'NumPrint',5

Data Types: double | single

'NumTuningIterations' — Number of tuning iterations

20 (default) | positive integer

Number of tuning iterations for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumTuningIterations' and a positive integer. This option is valid only for 'InitialLearningRate','auto'.

Example: 'NumTuningIterations',15

Data Types: double | single

'TuningSubsetSize' — Number of observations to use for tuning initial learning rate

$\min(100,n)$ (default) | positive integer value from 1 to n

Number of observations to use for tuning the initial learning rate, specified as the comma-separated pair consisting of `'TuningSubsetSize'` and a positive integer value from 1 to n . This option is valid only for `'InitialLearningRate'`, `'auto'`.

Example: `'TuningSubsetSize',25`

Data Types: `double` | `single`

SGD or LBFGS Options

'IterationLimit' — Maximum number of iterations

positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer. The default is 10000 for SGD and 1000 for LBFGS and mini-batch LBFGS.

Each pass through a batch is an iteration. Each pass through all of the data is an epoch. If the data is divided into k mini-batches, then every epoch is equivalent to k iterations.

Example: `'IterationLimit',250`

Data Types: `double` | `single`

'StepTolerance' — Convergence tolerance on the step size

1e-6 (default) | positive real scalar

Convergence tolerance on the step size, specified as the comma-separated pair consisting of `'StepTolerance'` and a positive real scalar. The `'lbfgs'` solver uses an absolute step tolerance, and the `'sgd'` solver uses a relative step tolerance.

Example: `'StepTolerance',0.000005`

Data Types: `double` | `single`

Mini-Batch LBFGS Options

'MiniBatchLBFGSIterations' — Maximum number of iterations per mini-batch LBFGS step

10 (default) | positive integer

Maximum number of iterations per mini-batch LBFGS step, specified as the comma-separated pair consisting of `'MiniBatchLBFGSIterations'` and a positive integer.

Example: 'MiniBatchLBFGSIterations', 15

Mini-batch LBFGS algorithm is a combination of SGD and LBFGS methods. Therefore, all of the name-value pair arguments that apply to SGD and LBFGS solvers also apply to the mini-batch LBFGS algorithm.

Data Types: double | single

Output Arguments

mdl — Neighborhood component analysis model for classification

FeatureSelectionNCAClassification object

Neighborhood component analysis model for classification, returned as a FeatureSelectionNCAClassification object.

Topics

“Tune Regularization Parameter to Detect Features Using NCA for Classification”

“Neighborhood Component Analysis (NCA) Feature Selection” on page 15-126

Introduced in R2016b

fsrnca

Feature selection using neighborhood component analysis for regression

Syntax

```
mdl = fsrnca(X,Y)
mdl = fsrnca(X,Y,Name,Value)
```

Description

`mdl = fsrnca(X,Y)` performs feature selection for regression using the predictors in X and responses in Y .

`fsrnca` learns the feature weights by a diagonal adaptation of neighborhood component analysis (NCA) with regularization.

`mdl = fsrnca(X,Y,Name,Value)` performs feature selection for regression with additional options specified by one or more name-value pair arguments.

Examples

Detect Relevant Features in Data Using NCA for Regression

Generate toy data where the response variable depends on the 3rd, 9th, and 15th predictors.

```
rng(0,'twister'); % For reproducibility
N = 100;
X = rand(N,20);
y = 1 + X(:,3)*5 + sin(X(:,9))./X(:,15) + 0.25*randn(N,1);
```

Fit the neighborhood component analysis model for regression.

```
mdl = fsrnca(X,y,'Verbose',1,'Lambda',0.5/N);
```

```
o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe
```

 Two norm of the final step = 1.111e-04, TolX = 1.000e-06
 Relative infinity norm of the final gradient = 2.596e-07, TolFun = 1.000e-06
 EXIT: Local minimum found.

Plot the selected features. The weights of the irrelevant features should be close to zero.

```

figure()
plot mdl.FeatureWeights, 'ro'
grid on
xlabel('Feature index')

```

```
ylabel('Feature weight')
```

fsrnca correctly detects the relevant predictors for this response.

Tune Regularization Parameter in NCA for Regression

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'robotarm.mat'))
```

The `robotarm` (`pumadyn32nm`) dataset is created using a robot arm simulator with 7168 training observations and 1024 test observations with 32 features [1][2]. This is a preprocessed version of the original data set. The data are preprocessed by subtracting off a linear regression fit, followed by normalization of all features to unit variance.

Perform neighborhood component analysis (NCA) feature selection for regression with the default λ (regularization parameter) value.

```
nca = fsrnca(Xtrain,ytrain,'FitMethod','exact', ...  
            'Solver','lbfgs');
```

Plot the selected values.

```
figure  
plot(nca.FeatureWeights,'ro')  
xlabel('Feature index')  
ylabel('Feature weight')  
grid on
```

More than half of the feature weights are nonzero. Compute the loss using the test set as a measure of the performance by using the selected features.

```
L = loss(nca,Xtest,ytest)
```

```
L =
```

```
0.0837
```

Try improving the performance. Tune the regularization parameter λ for feature selection using five-fold cross-validation. Tuning λ means finding the λ value that produces the minimum regression loss. To tune λ using cross-validation:

1. Partition the data into five folds. For each fold, `cvpartition` assigns 4/5th of the data as a training set, and 1/5th of the data as a test set.

```
rng(1) % For reproducibility
n = length(ytrain);
cvp = cvpartition(length(ytrain),'kfold',5);
numvalidsets = cvp.NumTestSets;
```

Assign the λ values for the search. Create an array to store the loss values.

```
lambdaval = linspace(0,50,20)*std(ytrain)/n;
lossvals = zeros(length(lambdaval),numvalidsets);
```

2. Train the NCA model for each λ value, using the training set in each fold.

3. Compute the regression loss for the corresponding test set in the fold using the NCA model. Record the loss value.

4. Repeat this for each λ value and each fold.

```
for i = 1:length(lambdaval)
    for k = 1:numvalidsets
        X = Xtrain(cvp.training(k),:);
        y = ytrain(cvp.training(k),:);
        Xvalid = Xtrain(cvp.test(k),:);
        yvalid = ytrain(cvp.test(k),:);

        nca = fsrnca(X,y,'FitMethod','exact', ...
            'Solver','minibatch-lbfgs','Lambda',lambdaval(i), ...
            'GradientTolerance',1e-4,'IterationLimit',30);
```

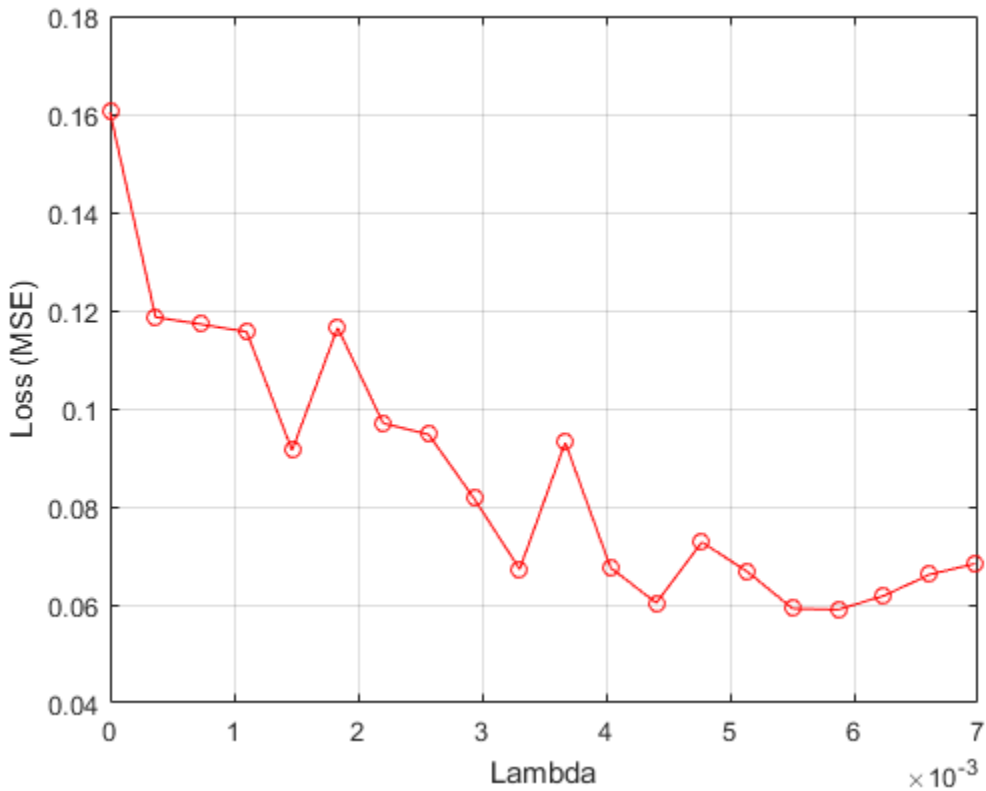

```
        lossvals(i,k) = loss(nca,Xvalid,yvalid,'LossFunction','mse');
    end
end
```

Compute the average loss obtained from the folds for each λ value.

```
meanloss = mean(lossvals,2);
```

Plot the mean loss versus the λ values.

```
figure
plot(lambdaval,meanloss,'ro-')
xlabel('Lambda')
ylabel('Loss (MSE)')
grid on
```

Find the λ value that gives the minimum loss value.

```
[~,idx] = min(meanloss)

bestlambda = lambdaval(idx)
bestloss = meanloss(idx)
```

```
idx =
```

```
    17
```

```
bestlambda =
```

```
    0.0059
```

```
bestloss =
```

```
    0.0590
```

Fit the NCA feature selection model for regression using the best λ value.

```
nca = fsrnca(Xtrain,ytrain,'FitMethod','exact', ...
            'Solver','lbfgs','Lambda',bestlambda);
```

Plot the selected features.

```
figure
plot(nca.FeatureWeights,'ro')
xlabel('Feature Index')
ylabel('Feature Weight')
grid on
```

Most of the feature weights are zero. `fsrnca` identifies the four most relevant features.

Compute the loss for the test set.

```
L = loss(nca,Xtest,ytest)
```

```
L =
```

```
0.0571
```

Tuning the regularization parameter, λ , eliminated more of the irrelevant features and improved the performance.

Compare NCA and ARD Feature Selection

This example uses the Abalone data [3][4] from the UCI Machine Learning Repository [5]. Download the data and save it in your current folder with the name 'abalone.data'.

Store the data into a table. Display the first seven rows.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);
tbl.Properties.VariableNames = {'Sex', 'Length', 'Diameter', 'Height', ...
    'WWeight', 'SWeight', 'VWeight', 'ShWeight', 'NoShellRings'};
tbl(1:7,:)
```

ans =

Sex	Length	Diameter	Height	WWeight	SWeight	VWeight	ShWeight
'M'	0.455	0.365	0.095	0.514	0.2245	0.101	0.15
'M'	0.35	0.265	0.09	0.2255	0.0995	0.0485	0.07
'F'	0.53	0.42	0.135	0.677	0.2565	0.1415	0.21
'M'	0.44	0.365	0.125	0.516	0.2155	0.114	0.155
'I'	0.33	0.255	0.08	0.205	0.0895	0.0395	0.055
'I'	0.425	0.3	0.095	0.3515	0.141	0.0775	0.12
'F'	0.53	0.415	0.15	0.7775	0.237	0.1415	0.33

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, the number of shell rings, shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Prepare the predictor and response variables for `fsrnca`. The last column of `tbl` contains the number of shell rings, which is the response variable. The first predictor variable, `sex`, is categorical. You must create dummy variables.

```
y = table2array(tbl(:,end));
X(:,1:3) = dummyvar(categorical(tbl.Sex));
X = [X, table2array(tbl(:,2:end-1))];
```

Use four-fold cross-validation to tune the regularization parameter in the NCA model. First partition the data into four folds.

```
n = length(y);
cvp = cvpartition(n, 'kfold', 4);
numtestsets = cvp.NumTestSets;
```

`cvpartition` divides the data into four partitions (folds). In each fold, about three-fourths of the data is assigned as a training set and one-fourth is assigned as a test set.

Generate a variety of λ (regularization parameter) values for fitting the model to determine the best λ value. Create a vector to collect the loss values from each fit.

```
lambdaval = linspace(0, 25, 20) * std(y) / n;
lossvals = zeros(length(lambdaval), numtestsets);
```

The rows of `lossvals` corresponds to the λ values and the columns correspond to the folds.

Fit the NCA model for regression using `fsrnca` to the data from each fold using each λ value. Compute the loss for each model using the test data from each fold.

```
for i = 1:length(lambdaval)
    for k = 1:numtestsets
        Xtrain = X(cvp.training(k), :);
        ytrain = y(cvp.training(k), :);
        Xtest = X(cvp.test(k), :);
        ytest = y(cvp.test(k), :);

        nca = fsrnca(Xtrain, ytrain, 'FitMethod', 'exact', ...
            'Solver', 'lbfgs', 'Lambda', lambdaval(i), 'Standardize', true);

        lossvals(i, k) = loss(nca, Xtest, ytest, 'LossFunction', 'mse');
    end
end
```

Compute the average loss for the folds, that is, compute the mean in the second dimension of `lossvals`.

```
meanloss = mean(lossvals, 2);
```

Plot the λ values versus the mean loss from the four folds.

```
figure
plot(lambdaval, meanloss, 'ro-')
```

```
xlabel('Lambda')
ylabel('Loss (MSE)')
grid on
```

Find the λ value that minimizes the mean loss.

```
[~,idx] = min(meanloss);
bestlambda = lambdaval(idx)
```

```
bestlambda =
```

```
0.0071
```

Compute the best loss value.

```
bestloss = meanloss(idx)
```

```
bestloss =
```

```
4.7799
```

Fit the NCA model on all of the data using the best λ value.

```
nca = fsrnca(X,y,'FitMethod','exact','Solver','lbfgs', ...
    'Verbose',1,'Lambda',bestlambda,'Standardize',1);
```

```
o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe
```

```

Compute the regression loss on the training data (resubstitution loss) for the trained model.

```
L = resubLoss(gprMdl)
```

```
L =
```

```
4.0064
```

The smallest cross-validated loss using `fsrcna` is comparable to the loss obtained using a GPR model with an ARD kernel.

- “Robust Feature Selection Using NCA for Regression” on page 15-107

Input Arguments

X — Predictor variable values

n-by-*p* matrix

Predictor variable values, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables.

Data Types: `single` | `double`

Y — Response values

numeric real vector of length *n*

Response values, specified as a numeric real vector of length *n*, where *n* is the number of observations.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `'Solver','sgd','Weights',W,'Lambda',0.0003` specifies the solver as the stochastic gradient descent, the observation weights as the values in the vector *W*, and sets the regularization parameter at 0.0003.

Fitting Options

'FitMethod' — Method for fitting the model

`'exact'` (default) | `'none'` | `'average'`

Method for fitting the model, specified as the comma-separated pair consisting of `'FitMethod'` and one of the following:

- `'exact'` — Performs fitting using all of the data.
- `'none'` — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fsrnca`.

- **'average'** — Divides the data into partitions (subsets), fits each partition using the **exact** method, and returns the average of the feature weights. You can specify the number of partitions using the **NumPartitions** name-value pair argument.

Example: `'FitMethod', 'none'`

Data Types: `char`

'NumPartitions' — Number of partitions

`max(2, min(10, n))` (default) | integer between 2 and n

Number of partitions to split the data for using with `'FitMethod', 'average'` option, specified as the comma-separated pair consisting of `'NumPartitions'` and an integer value between 2 and n , where n is the number of observations.

Example: `'NumPartitions', 15`

Data Types: `double` | `single`

'Lambda' — Regularization parameter

$1/n$ (default) | nonnegative scalar

Regularization parameter, specified as the comma-separated pair consisting of `'Lambda'` and a nonnegative scalar.

For n observations, the best **Lambda** value that minimizes the generalization error of the NCA model is expected to be a multiple of $1/n$.

Example: `'Lambda', 0.002`

Data Types: `double` | `single`

'LengthScale' — Width of the kernel

1 (default) | positive real scalar

Width of the kernel, specified as the comma-separated pair consisting of `'LengthScale'` and a positive real scalar.

A length scale value of 1 is sensible when all predictors are on the same scale. If the predictors in X are of very different magnitudes, then consider standardizing the predictor values using `'Standardize', true` and setting `'LengthScale', 1`.

Example: `'LengthScale', 1.5`

Data Types: `double` | `single`

'InitialFeatureWeights' — Initial feature weights

ones($p, 1$) (default) | p -by-1 vector of real positive scalars

Initial feature weights, specified as the comma-separated pair consisting of 'InitialFeatureWeights' and a p -by-1 vector of real positive scalars, where p is the number of predictors in the training data.

The regularized objective function for optimizing feature weights is nonconvex. As a result, using different initial feature weights can give different results. Setting all initial feature weights to 1 generally works well, but in some cases, random initialization using `rand(p, 1)` can give better quality solutions.

Data Types: double | single

'Weights' — Observation weights

n -by-1 vector of 1s (default) | n -by-1 vector of real positive scalars

Observation weights, specified as the comma-separated pair consisting of 'ObservationWeights' and an n -by-1 vector of real positive scalars. Use observation weights to specify higher importance of some observations compared to others. The default weights assign equal importance to all observations.

Data Types: double | single

'Standardize' — Indicator for standardizing predictor data

0 (default) | 1

Indicator for standardizing the predictor data, specified as the comma-separated pair consisting of 'Standardize' and either 0 (false) or 1 (true). For more information, see “Impact of Standardization” on page 15-131.

Example: 'Standardize', 1

Data Types: logical

'Verbose' — Verbosity level indicator

0 (default) | 1 | >1

Verbosity level indicator for the convergence summary display, specified as the comma-separated pair consisting of 'Verbose' and one of the following:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function values

- `> 1` — More convergence information, depending on the fitting algorithm

When using `'minibatch-lbfgs'` solver and verbosity level `> 1`, the convergence information includes iteration the log from intermediate mini-batch LBFGS fits.

Example: `'Verbose', 1`

Data Types: `double` | `single`

'Solver' — Solver type

`'lbfgs'` | `'sgd'` | `'minibatch-lbfgs'`

Solver type for estimating feature weights, specified as the comma-separated pair consisting of `'Solver'` and one of the following:

- `'lbfgs'` — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- `'sgd'` — Stochastic gradient descent (SGD) algorithm
- `'minibatch-lbfgs'` — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Default is `'lbfgs'` for $n \leq 1000$, and `'sgd'` for $n > 1000$.

Example: `'solver', 'minibatch-lbfgs'`

Data Types: `char`

'LossFunction' — Loss function

`'mad'` (default) | `'mse'` | `'epsiloninsensitive'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFunction'` and one of the following:

- `'mad'` — Mean absolute deviation, defined as

$$\frac{1}{n} \sum_{i=1}^n |y_i - y_j|,$$

where y_i is the true response for \mathbf{x}_i , and t_i is the predicted response using the NCA regression model.

- `'mse'` — Mean squared error, defined as

$$\frac{1}{n} \sum_{i=1}^n (y_i - y_j)^2.$$

- 'epsiloninsensitive' — ϵ -insensitive loss function, defined as

$$l(y_i, y_j) = \max(0, |y_i - y_j| - \epsilon).$$

This loss function is more robust to outliers than mean squared error or mean absolute deviation.

- Function handle — Custom loss function. For example for the 'LossFunction', L name-value pair, L must have the following form:

`L = lossFcn(Yn, Ym)`

`Yn` is an n -by-1 vector and `Ym` is an m -by-1 vector. `L` is an n -by- m matrix of loss values such that `L(i, j)` is the loss value for `Yn(i)` and `Ym(j)`.

Example: 'LossFunction', 'mse'

Data Types: char | function_handle

'Epsilon' — Epsilon value

`iqr(Y)/13.49` (default) | nonnegative real scalar

Epsilon value for the 'LossFunction', 'epsiloninsensitive' option, specified as the comma-separated pair consisting of 'LossFunction' and a nonnegative real scalar. The default value is an estimate of the sample standard deviation using the interquartile range of the response variable.

Example: 'Epsilon', 0.1

Data Types: double | single

'CacheSize' — Memory size

1000MB (default) | integer

Memory size, in MB, to use for objective function and gradient computation, specified as the comma-separated pair consisting of 'CacheSize' and an integer.

Example: 'CacheSize', 1500MB

Data Types: double | single

LBFGS Options

'HessianHistorySize' — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of history buffer for Hessian approximation for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. At each iteration the function uses the most recent HessianHistorySize iterations to build an approximation to the inverse Hessian.

Example: 'HessianHistorySize',20

Data Types: double | single

'InitialStepSize' — Initial step size

'auto' (default) | positive real scalar

Initial step size for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'InitialStepSize' and a positive real scalar. By default, the function determines the initial step size automatically.

Data Types: double | single

'LineSearchMethod' — Line search method

'weakwolfe' (default) | 'strongwolfe' | 'backtracking'

Line search method, specified as the comma-separated pair consisting of 'LineSearchMethod' and one of the following:

- 'weakwolfe' — Weak Wolfe line search
- 'strongwolfe' — Strong Wolfe line search
- 'backtracking' — Backtracking line search

Example: 'LineSearchMethod','backtracking'

Data Types: char

'MaxLineSearchIterations' — Maximum number of line search iterations

20 (default) | positive integer

Maximum number of line search iterations, specified as the comma-separated pair consisting of 'MaxLineSearchIterations' and a positive integer.

Example: 'MaxLineSearchIterations',25

Data Types: double | single

'GradientTolerance' — Relative convergence tolerance

1e-6 (default) | positive real scalar

Relative convergence tolerance on the gradient norm for solver `lbfgs`, specified as the comma-separated pair consisting of `'GradientTolerance'` and a positive real scalar.

Example: `'GradientTolerance',0.000002`

Data Types: double | single

SGD Options

'InitialLearningRate' — Initial learning rate for 'sgd' solver

'auto' (default) | positive real scalar

Initial learning rate for the `'sgd'` solver, specified as the comma-separated pair consisting of `'InitialLearningRate'` and a positive real scalar.

When using solver type `'sgd'`, the learning rate decays over iterations starting with the value specified for `'InitialLearningRate'`.

The default `'auto'` means that the initial learning rate is determined using experiments on small subsets of data. Use the `NumTuningIterations` name-value pair argument to specify the number of iterations for automatically tuning the initial learning rate. Use the `TuningSubsetSize` name-value pair argument to specify the number of observations to use for automatically tuning the initial learning rate.

For solver type `'minibatch-lbfgs'`, you can set `'InitialLearningRate'` to a very high value. In this case, the function applies LBFGS to each mini-batch separately with initial feature weights from the previous mini-batch.

To make sure the chosen initial learning rate decreases the objective value with each iteration, plot the `Iteration` versus the `Objective` values saved in the `mdl.FitInfo` property.

You can use the `refit` method with `'InitialFeatureWeights'` equal to `mdl.FeatureWeights` to start from the current solution and run additional iterations

Example: `'InitialLearningRate',0.9`

Data Types: double | single

'MiniBatchSize' — Number of observations to use in each batch for the 'sgd' solver
min(10, n) (default) | positive integer value from 1 to n

Number of observations to use in each batch for the 'sgd' solver, specified as the comma-separated pair consisting of 'MiniBatchSize' and a positive integer from 1 to n .

Example: 'MiniBatchSize',25

Data Types: double | single

'PassLimit' — Maximum number of passes for solver 'sgd'
5 (default) | positive integer

Maximum number of passes through all n observations for solver 'sgd', specified as the comma-separated pair consisting of 'PassLimit' and a positive integer. Each pass through all of the data is called an epoch.

Example: 'PassLimit',10

Data Types: double | single

'NumPrint' — Frequency of batches for displaying convergence summary
10 (default) | positive integer value

Frequency of batches for displaying convergence summary for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumPrint' and a positive integer. This argument applies when the 'Verbose' value is greater than 0. NumPrint mini-batches are processed for each line of the convergence summary that is displayed on the command line.

Example: 'NumPrint',5

Data Types: double | single

'NumTuningIterations' — Number of tuning iterations
20 (default) | positive integer

Number of tuning iterations for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumTuningIterations' and a positive integer. This option is valid only for 'InitialLearningRate','auto'.

Example: 'NumTuningIterations',15

Data Types: double | single

'TuningSubsetSize' — Number of observations to use for tuning initial learning rate
 $\min(100,n)$ (default) | positive integer value from 1 to n

Number of observations to use for tuning the initial learning rate, specified as the comma-separated pair consisting of **'TuningSubsetSize'** and a positive integer value from 1 to n . This option is valid only for **'InitialLearningRate'**, **'auto'**.

Example: **'TuningSubsetSize'**,25

Data Types: double | single

SGD or LBFGS Options

'IterationLimit' — Maximum number of iterations
 positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of **'IterationLimit'** and a positive integer. The default is 10000 for SGD and 1000 for LBFGS and mini-batch LBFGS.

Each pass through a batch is an iteration. Each pass through all of the data is an epoch. If the data is divided into k mini-batches, then every epoch is equivalent to k iterations.

Example: **'IterationLimit'**,250

Data Types: double | single

'StepTolerance' — Convergence tolerance on the step size
 $1e-6$ (default) | positive real scalar

Convergence tolerance on the step size, specified as the comma-separated pair consisting of **'StepTolerance'** and a positive real scalar. The **'lbfgs'** solver uses an absolute step tolerance, and the **'sgd'** solver uses a relative step tolerance.

Example: **'StepTolerance'**,0.000005

Data Types: double | single

Mini-batch LBFGS Options

'MiniBatchLBFGSIterations' — Maximum number of iterations per mini-batch LBFGS step
 10 (default) | positive integer

Maximum number of iterations per mini-batch LBFGS step, specified as the comma-separated pair consisting of 'MiniBatchLBFGSIterations' and a positive integer.

Example: 'MiniBatchLBFGSIterations',15

Mini-batch LBFGS algorithm is a combination of SGD and LBFGS methods. Therefore, all of the name-value pair arguments that apply to SGD and LBFGS solvers also apply to the mini-batch LBFGS algorithm.

Data Types: double | single

Output Arguments

mdl — Neighborhood component analysis model for regression

FeatureSelectionNCARegression object

Neighborhood component analysis model for regression, returned as a FeatureSelectionNCARegression object.

Introduced in R2016b

fstat

F mean and variance

Syntax

```
[M,V] = fstat(V1,V2)
```

Description

[M,V] = fstat(V1,V2) returns the mean of and variance for the *F* distribution with numerator degrees of freedom V1 and denominator degrees of freedom V2. V1 and V2 can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of M and V. A scalar input for V1 or V2 is expanded to a constant arrays with the same dimensions as the other input.

The mean of the *F* distribution for values of ν_2 greater than 2 is

$$\frac{\nu_2}{\nu_2 - 2}$$

The variance of the *F* distribution for values of ν_2 greater than 4 is

$$\frac{2\nu_2^2(\nu_1 + \nu_2 - 2)}{\nu_1(\nu_2 - 2)^2(\nu_2 - 4)}$$

The mean of the *F* distribution is undefined if ν_2 is less than 3. The variance is undefined for ν_2 less than 5.

Examples

fstat returns NaN when the mean and variance are undefined.

```
[m,v] = fstat(1:5,1:5)
```

```
m =  
    NaN    NaN    3.0000    2.0000    1.6667  
v =  
    NaN    NaN    NaN    NaN    8.8889
```

Introduced before R2006a

fsurfht

Interactive contour plot

Syntax

```
fsurfht(fun,xlims,ylim)  
fsurfht(fun,xlims,ylim,p1,p2,p3,p4,p5)
```

Description

`fsurfht(fun,xlims,ylim)` is an interactive contour plot of the function specified by the text variable `fun`. The x -axis limits are specified by `xlims` in the form `[xmin xmax]`, and the y -axis limits are specified by `ylim` in the form `[ymin ymax]`.

`fsurfht(fun,xlims,ylim,p1,p2,p3,p4,p5)` allows for five optional parameters that you can supply to the function `fun`.

The intersection of the vertical and horizontal reference lines on the plot defines the current x value and y value. You can drag these reference lines and watch the calculated z -values (at the top of the plot) update simultaneously. Alternatively, you can type the x value and y value into editable text fields on the x -axis and y -axis.

Examples

Plot the Gaussian likelihood function for the `gas.mat` data.

```
load gas
```

Create a function containing the following commands, and name it `gauslike.m`.

```
function z = gauslike(mu,sigma,p1)  
n = length(p1);  
z = ones(size(mu));  
for i = 1:n  
z = z .* (normpdf(p1(i),mu,sigma));  
end
```

The `gauslike` function calls `normpdf`, treating the data sample as fixed and the parameters μ and σ as variables. Assume that the gas prices are normally distributed, and plot the likelihood surface of the sample.

```
fsurfht('gauslike',[112 118],[3 5],price1)
```

The sample mean is the x value at the maximum, but the sample standard deviation is *not* the y value at the maximum.

```
mumax = mean(price1)
mumax =
    115.1500
sigmamax = std(price1)*sqrt(19/20)
sigmamax =
```

3.7719

Introduced before R2006a

fullfact

Full factorial design

Syntax

```
dFF = fullfact(levels)
```

Description

`dFF = fullfact(levels)` gives factor settings `dFF` for a full factorial design with n factors, where the number of levels for each factor is given by the vector `levels` of length n . `dFF` is m -by- n , where m is the number of treatments in the full-factorial design. Each row of `dFF` corresponds to a single treatment. Each column contains the settings for a single factor, with integer values from one to the number of levels.

Examples

The following generates an eight-run full-factorial design with two levels in the first factor and four levels in the second factor:

```
dFF = fullfact([2 4])
dFF =
  1  1
  2  1
  1  2
  2  2
  1  3
  2  3
  1  4
  2  4
```

`ff2n`

Introduced before R2006a

gagerr

Gage repeatability and reproducibility study

Syntax

```
gagerr(y, {part, operator})  
gagerr(y, GROUP)  
gagerr(y, part)  
gagerr(..., param1, val1, param2, val2, ...)  
[TABLE, stats] = gagerr(...)
```

Description

`gagerr(y, {part, operator})` performs a gage repeatability and reproducibility study on measurements in `y` collected by `operator` on `part`. `y` is a column vector containing the measurements on different parts. `part` and `operator` are categorical variables, numeric vectors, character matrices, or cell arrays of character vectors. The number of elements in `part` and `operator` should be the same as in `y`.

`gagerr` prints a table in the command window in which the decomposition of variance, standard deviation, study var (5.15 x standard deviation) are listed with respective percentages for different sources. Summary statistics are printed below the table giving the number of distinct categories (NDC) and the percentage of Gage R&R of total variations (PRR).

`gagerr` also plots a bar graph showing the percentage of different components of variations. Gage R&R, repeatability, reproducibility, and part-to-part variations are plotted as four vertical bars. Variance and study var are plotted as two groups.

To determine the capability of a measurement system using NDC, use the following guidelines:

- If $NDC > 5$, the measurement system is capable.
- If $NDC < 2$, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

To determine the capability of a measurement system using PRR, use the following guidelines:

- If $PRR < 10\%$, the measurement system is capable.
- If $PRR > 30\%$, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

`gagerr(y, GROUP)` performs a gage R&R study on measurements in `y` with `part` and `operator` represented in `GROUP`. `GROUP` is a numeric matrix whose first and second columns specify different parts and operators, respectively. The number of rows in `GROUP` should be the same as the number of elements in `y`.

`gagerr(y, part)` performs a gage R&R study on measurements in `y` without operator information. The assumption is that all variability is contributed by `part`.

`gagerr(..., param1, val1, param2, val2, ...)` performs a gage R&R study using one or more of the following parameter name/value pairs:

- `'spec'` — A two-element vector that defines the lower and upper limit of the process, respectively. In this case, summary statistics printed in the command window include Precision-to-Tolerance Ratio (PTR). Also, the bar graph includes an additional group, the percentage of tolerance.

To determine the capability of a measurement system using PTR, use the following guidelines:

- If $PTR < 0.1$, the measurement system is capable.
- If $PTR > 0.3$, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.
- `'printtable'` — A value `'on'` or `'off'` that indicates whether the tabular output should be printed in the command window or not. The default value is `'on'`.
- `'printgraph'` — A value `'on'` or `'off'` that indicates whether the bar graph should be plotted or not. The default value is `'on'`.
- `'randomoperator'` — A logical value, `true` or `false`, that indicates whether the effect of `operator` is random or not. The default value is `true`.
- `'model'` — The model to use, specified by one of:
 - `'linear'` — Main effects only (default)
 - `'interaction'` — Main effects plus two-factor interactions
 - `'nested'` — Nest operator in `part`

The default value is `'linear'`.

`[TABLE, stats] = gagerr(...)` returns a 6-by-5 matrix `TABLE` and a structure `stats`. The columns of `TABLE`, from left to right, represent variance, percentage of variance, standard deviations, study var, and percentage of study var. The rows of `TABLE`, from top to bottom, represent different sources of variations: gage R&R, repeatability, reproducibility, operator, operator and part interactions, and part. `stats` is a structure containing summary statistics for the performance of the measurement system. The fields of `stats` are:

- `ndc` — Number of distinct categories
- `prp` — Percentage of gage R&R of total variations
- `ptr` — Precision-to-tolerance ratio. The value is NaN if the parameter `'spec'` is not given.

Examples

Gage R&R Study

Simulate a measurement system by randomly generating the operators, parts, and the measurements, `y`, operators do on the parts.

```
rng(1234, 'twister')           % for reproducibility
y = randn(100,1);              % measurements
part = ceil(3*rand(100,1));     % parts
operator = ceil(4*rand(100,1)); % operators
```

Conduct a gage R&R study for this system using a mixed ANOVA model without interactions.

```
gagerr(y, {part, operator}, 'randomoperator', true)
```

Introduced in R2006b

gamcdf

Gamma cumulative distribution function

Syntax

```
gamcdf(x, a, b)
[p, plo, pup] = gamcdf(x, a, b, pcov, alpha)
[p, plo, pup] = gamcdf( ____, 'upper' )
```

Description

`gamcdf(x, a, b)` returns the gamma cdf at each of the values in `x` using the corresponding shape parameters in `a` and scale parameters in `b`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `a` and `b` must be positive.

`[p, plo, pup] = gamcdf(x, a, b, pcov, alpha)` produces confidence bounds for `p` when the input parameters `a` and `b` are estimates. `pcov` is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies $100(1 - \alpha)\%$ confidence bounds. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p, plo, pup] = gamcdf(____, 'upper')` returns the complement of the gamma cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the 'upper' argument with any of the previous syntaxes.

The gamma cdf is

$$p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt$$

The result, p , is the probability that a single observation from a gamma distribution with parameters a and b will fall in the interval $[0, x]$.

`gammainc` is the gamma distribution with b fixed at 1.

Examples

Compute Gamma Distribution CDF

The mean of the gamma distribution is the product of the parameters, ab . In this example, the mean approaches the median as it increases (i.e., the distribution becomes more symmetric).

```
a = 1:6;  
b = 5:10;  
prob = gamcdf(a.*b,a,b)
```

```
prob =
```

```
    0.6321    0.5940    0.5768    0.5665    0.5595    0.5543
```

Extended Capabilities

gamfit

Gamma parameter estimates

Syntax

```
phat = gamfit(data)
[phat,pci] = gamfit(data)
[phat,pci] = gamfit(data,alpha)
[...] = gamfit(data,alpha,censoring,freq,options)
```

Description

`phat = gamfit(data)` returns the maximum likelihood estimates (MLEs) for the parameters of the gamma distribution given the data in vector `data`.

`[phat,pci] = gamfit(data)` returns MLEs and 95% percent confidence intervals. The first row of `pci` is the lower bound of the confidence intervals; the last row is the upper bound.

`[phat,pci] = gamfit(data,alpha)` returns $100(1 - \alpha)\%$ confidence intervals. For example, `alpha = 0.01` yields 99% confidence intervals.

`[...] = gamfit(data,alpha,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(data,alpha,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any nonnegative values.

`[...] = gamfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The gamma fit function accepts an `options` structure which can be created using the function `statset`. Enter `statset('gamfit')` to see the names and default values of the parameters that `gamfit` accepts in the `options` structure.

Examples

Fit a gamma distribution to random data generated from a specified gamma distribution:

```
a = 2; b = 4;  
data = gamrnd(a,b,100,1);
```

```
[p,ci] = gamfit(data)  
p =  
 2.1990  3.7426  
ci =  
 1.6840  2.8298  
 2.7141  4.6554
```

prob.GammaDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Gamma probability distribution object

Description

`prob.GammaDistribution` is an object consisting of parameters, a model description, and sample data for a gamma probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitter app.

Construction

`pd = makedist('Gamma')` creates a gamma probability distribution object using the default parameter values.

`pd = makedist('Gamma', 'a', a, 'b', b)` creates a gamma probability distribution object using the specified parameter values.

Input Arguments

a — Shape parameter

1 (default) | positive scalar value

Shape parameter for the gamma distribution, specified as a positive scalar value.

Data Types: `single` | `double`

b — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the gamma distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Properties

a — Shape parameter

positive scalar value

Shape parameter for the gamma distribution, stored as a positive scalar value.

Data Types: `single` | `double`

b — Scale parameter

nonnegative scalar value

Scale parameter for the gamma distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

character vector

Probability distribution name, stored as a character vector. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: single | double

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: single | double

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

Distribution parameter descriptions, stored as a cell array of character vectors. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: logical

ParameterNames — Distribution parameter names

cell array of character vectors

Distribution parameter names, stored as a cell array of character vectors. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative log likelihood of probability distribution object

paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Examples

Create a Gamma Distribution Object Using Default Parameters

Create a gamma distribution object using the default parameter values.

```
pd = makedist('Gamma')
```

```
pd =  
GammaDistribution  
  
Gamma distribution  
a = 1  
b = 1
```

Create a Gamma Distribution Object Using Specified Parameters

Create a gamma distribution object by specifying the parameter values.

```
pd = makedist('Gamma', 'a',2,'b',4)
```

```
pd =  
GammaDistribution  
  
Gamma distribution  
a = 2  
b = 4
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
8
```

Definitions

Gamma Distribution

The gamma distribution is a two-parameter family of distributions used to model sums of exponentially distributed random variables. The chi-square and the exponential distributions, which are children of the gamma distribution, are one-parameter distributions that fix one of the two gamma parameters.

The gamma distribution uses the following parameters.

Parameter	Description	Support
a	Shape parameter	$a > 0$
b	Scale parameter	$b \geq 0$

The probability density function (pdf) is

$$f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}} \quad ; \quad x > 0,$$

where $\Gamma(\cdot)$ is the Gamma function.

Class Attributes (MATLAB)

Property Attributes (MATLAB)

gaminv

Gamma inverse cumulative distribution function

Syntax

```
X = gaminv(P,A,B)
[X,XLO,XUP] = gamcdf(P,A,B,pcov,alpha)
```

Description

`X = gaminv(P,A,B)` computes the inverse of the gamma cdf with shape parameters in **A** and scale parameters in **B** for the corresponding probabilities in **P**. **P**, **A**, and **B** can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in **A** and **B** must all be positive, and the values in **P** must lie on the interval [0 1].

The gamma inverse function in terms of the gamma cdf is

$$x = F^{-1}(p | a, b) = \{x : F(x | a, b) = p\}$$

where

$$p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt$$

`[X,XLO,XUP] = gamcdf(P,A,B,pcov,alpha)` produces confidence bounds for **P** when the input parameters **A** and **B** are estimates. **pcov** is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. **alpha** has a default value of 0.05, and specifies 100(1 - **alpha**)% confidence bounds. **PLO** and **PUP** are arrays of the same size as **P** containing the lower and upper confidence bounds.

Examples

This example shows the relationship between the gamma cdf and its inverse function.

```
a = 1:5;  
b = 6:10;  
x = gaminv(gamcdf(1:5,a,b),a,b)  
x =  
    1.0000    2.0000    3.0000    4.0000    5.0000
```

Algorithms

There is no known analytical solution to the integral equation above. `gaminv` uses an iterative approach (Newton's method) to converge on the solution.

Extended Capabilities

Topics

“Gamma Distribution” on page B-47

Introduced before R2006a

gamlike

Gamma negative log-likelihood

Syntax

```
nlogL = gamlike(params,data)
[nlogL,AVAR] = gamlike(params,data)
```

Description

`nlogL = gamlike(params,data)` returns the negative of the gamma log-likelihood of the parameters, `params`, given `data`. `params(1)=A`, shape parameters, and `params(2)=B`, scale parameters.

`[nlogL,AVAR] = gamlike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates when the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`[...] = gamlike(params,data,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(params,data,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any non-negative values.

`gamlike` is a utility function for maximum likelihood estimation of the gamma distribution. Since `gamlike` returns the negative gamma log-likelihood function, minimizing `gamlike` using `fminsearch` is the same as maximizing the likelihood.

Examples

Compute the negative log-likelihood of parameter estimates computed by the `gamfit` function:

```
a = 2; b = 3;
r = gamrnd(a,b,100,1);

[nlogL,AVAR] = gamlike(gamfit(r),r)
nlogL =
    267.5648
AVAR =
    0.0788  -0.1104
   -0.1104  0.1955
```

gampdf

Gamma probability density function

Syntax

```
Y = gampdf(X,A,B)
```

Description

`Y = gampdf(X,A,B)` computes the gamma pdf at each of the values in `X` using the corresponding shape parameters in `A` and scale parameters in `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `A` and `B` must all be positive, and the values in `X` must lie on the interval $[0 \infty)$.

The gamma pdf is

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

The gamma probability density function is useful in reliability models of lifetimes. The gamma distribution is more flexible than the exponential distribution in that the probability of a product surviving an additional period may depend on its current age. The exponential and χ^2 functions are special cases of the gamma function.

Examples

The exponential distribution is a special case of the gamma distribution.

```
mu = 1:5;
```

```
y = gampdf(1,1,mu)  
y =
```

```
0.3679 0.3033 0.2388 0.1947 0.1637
y1 = exppdf(1,mu)
y1 =
0.3679 0.3033 0.2388 0.1947 0.1637
```

gamrnd

Gamma random numbers

Syntax

```
R = gamrnd(A,B)
R = gamrnd(A,B,m,n,...)
R = gamrnd(A,B,[m,n,...])
```

Description

`R = gamrnd(A,B)` generates random numbers from the gamma distribution with shape parameters in `A` and scale parameters in `B`. `A` and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `A` or `B` is expanded to a constant array with the same dimensions as the other input.

`R = gamrnd(A,B,m,n,...)` or `R = gamrnd(A,B,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the gamma distribution with parameters `A` and `B`. `A` and `B` can each be scalars or arrays of the same size as `R`.

Examples

```
n1 = gamrnd(1:5,6:10)
n1 =
    9.1132    12.8431    24.8025    38.5960   106.4164
```

```
n2 = gamrnd(5,10,[1 5])
n2 =
    30.9486    33.5667    33.6837    55.2014    46.8265
```

```
n3 = gamrnd(2:6,3,1,5)
n3 =
    12.8715    11.3068     3.0982    15.6012    21.6739
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

gamstat

Gamma mean and variance

Syntax

```
[M,V] = gamstat(A,B)
```

Description

`[M,V] = gamstat(A,B)` returns the mean of and variance for the gamma distribution with shape parameters in **A** and scale parameters in **B**. **A** and **B** can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of **M** and **V**. A scalar input for **A** or **B** is expanded to a constant array with the same dimensions as the other input.

The mean of the gamma distribution with parameters a and b is ab . The variance is ab^2 .

Examples

```
[m,v] = gamstat(1:5,1:5)
```

```
m =
```

```
1 4 9 16 25
```

```
v =
```

```
1 8 27 64 125
```

```
[m,v] = gamstat(1:5,1./(1:5))
```

```
m =
```

```
1 1 1 1 1
```

```
v =
```

```
1.0000 0.5000 0.3333 0.2500 0.2000
```

ge

Class: grandstream

Greater than or equal relation for handles

Syntax

`h1 >= h2`

Description

`h1 >= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = ge(h1, h2)` stores the result in a logical array of the same dimensions.

prob.GeneralizedExtremeValueDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Generalized extreme value probability distribution object

Description

`prob.GeneralizedExtremeValueDistribution` is an object consisting of parameters, a model description, and sample data for a generalized extreme value probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitter app.

Construction

`pd = makedist('GeneralizedExtremeValue')` creates a generalized extreme value probability distribution object using the default parameter values.

`pd = makedist('GeneralizedExtremeValue', 'k', k, 'sigma', sigma, 'mu', mu)` creates a generalized extreme value probability distribution object using the specified parameter values.

Input Arguments

k — Shape parameter

0 (default) | scalar value

Shape parameter for the generalized extreme value distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the generalized extreme value distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

mu — Location parameter

0 (default) | scalar value

Location parameter for the generalized extreme value distribution, specified as a scalar value.

Data Types: `single` | `double`

Properties

k — Shape parameter

scalar value

Shape parameter of the generalized extreme value distribution, stored as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the generalized extreme value distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

mu — Location parameter

scalar value

Location parameter of the generalized extreme value distribution, stored as a scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

character vector

Probability distribution name, stored as a character vector. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If **IsTruncated** equals 0, the distribution is not truncated. If **IsTruncated** equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

Distribution parameter descriptions, stored as a cell array of character vectors. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: logical

ParameterNames — Distribution parameter names

cell array of character vectors

Distribution parameter names, stored as a cell array of character vectors. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

`cdf`

Cumulative distribution function of probability distribution object

icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative log likelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Examples

Create a Generalized Extreme Value Distribution Object Using Default Parameters

Create a generalized extreme value distribution object using the default parameter values.

```
pd = makedist('GeneralizedExtremeValue')
```

```
pd =
```

```
GeneralizedExtremeValueDistribution
```

```
Generalized Extreme Value distribution
```

```
k = 0
sigma = 1
mu = 0
```

Create a Generalized Extreme Value Distribution Object Using Specified Parameters

Create a generalized extreme value distribution object by specifying values for the parameters.

```
pd = makedist('GeneralizedExtremeValue', 'k',0, 'sigma',2, 'mu',1)
```

```
pd =
  GeneralizedExtremeValueDistribution

  Generalized Extreme Value distribution
  k = 0
  sigma = 2
  mu = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
  2.1544
```

Definitions

Generalized Extreme Value Distribution

The generalized extreme value distribution is often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. It combines three simpler distributions into a single form, allowing a continuous range of possible shapes that include all three of the simpler distributions.

The three distribution types correspond to the limiting distribution of block maxima from different classes of underlying distributions:

- Type 1 — Distributions whose tails decrease exponentially, such as the normal distribution
- Type 2 — Distributions whose tails decrease as a polynomial, such as Student's t distribution
- Type 3 — Distributions whose tails are finite, such as the beta distribution

The generalized extreme value distribution uses the following parameters.

Parameter	Description	Support
k	Shape parameter	$-\infty \leq k \leq \infty$
σ	Scale parameter	$\sigma \geq 0$
μ	Location parameter	$-\infty \leq \mu \leq \infty$

The probability density function (pdf) for a Type 1 distribution, where shape parameter $k = 0$, is

$$f(x | 0, \mu, \sigma) = \left(\frac{1}{\sigma} \right) \exp \left(-\exp \left(-\frac{(x - \mu)}{\sigma} \right) - \frac{(x - \mu)}{\sigma} \right) ; \quad -\infty < x < \infty.$$

When $k \neq 0$, the pdf is

$$f(x | k, \mu, \sigma) = \left(\frac{1}{\sigma} \right) \exp \left(-\left(1 + k \frac{(x - \mu)}{\sigma} \right)^{\frac{1}{k}} \right) \left(1 + k \frac{(x - \mu)}{\sigma} \right)^{-1 - \frac{1}{k}}$$

for

$$1 + k \frac{(x - \mu)}{\sigma} > 0.$$

For the Type 2 case, $k > 0$ and $x \geq \mu - \frac{\sigma}{k}$. For the Type 3 case, $k < 0$ and $x < \mu - \frac{\sigma}{k}$.

Class Attributes (MATLAB)

Property Attributes (MATLAB)

GeneralizedLinearMixedModel class

Generalized linear mixed-effects model class

Description

A `GeneralizedLinearMixedModel` object represents a regression model of a response variable that contains both fixed and random effects. The object comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a generalized linear mixed-effects (GLME) model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

Construction

You can fit a generalized linear mixed-effects (GLME) model to sample data using `fitglme(tbl, formula)`. For more information, see `fitglme`.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-58). You must specify the model for the variables using `formula`.

Data Types: table

formula — Formula for model specification

character vector of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a character vector of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For a full description, see `Formula`.

Example: `'y ~ treatment +(1|block)'`

Properties

Coefficients — Estimates of fixed-effects coefficients

dataset array

Estimates of fixed-effects coefficients and related statistics, stored as a dataset array that has one row for each coefficient and the following columns:

- **Name** — Name of the coefficient
- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — *t*-statistic for a test that the coefficient is equal to 0
- **DF** — Degrees of freedom associated with the *t* statistic
- **pValue** — *p*-value for the *t*-statistic
- **Lower** — Lower confidence limit
- **Upper** — Upper confidence limit

To obtain any of these columns as a vector, index into the property using dot notation.

Use the `coefTest` method to perform other tests on the coefficients.

CoefficientCovariance — Covariance of estimated fixed-effects vector

matrix

Covariance of estimated fixed-effects vector, stored as a matrix.

Data Types: `single` | `double`

CoefficientNames — Names of fixed-effects coefficients

cell array of character vectors

Names of fixed-effects coefficients, stored as a cell array of character vectors. The label for the coefficient of the constant term is (`Intercept`). The labels for other coefficients indicate the terms that they multiply. When the term includes a categorical predictor, the label also indicates the level of that predictor.

Data Types: `cell`

DFE — Degrees of freedom for error

positive integer value

Degrees of freedom for error, stored as a positive integer value. DFE is the number of observations minus the number of estimated coefficients.

DFE contains the degrees of freedom corresponding to the 'Residual' method of calculating denominator degrees of freedom for hypothesis tests on fixed-effects coefficients. If n is the number of observations and p is the number of fixed-effects coefficients, then DFE is equal to $n - p$.

Data Types: double

Dispersion — Model dispersion parameter

scalar value

Model dispersion parameter, stored as a scalar value. The dispersion parameter defines the conditional variance of the response.

For observation i , the conditional variance of the response y_i , given the conditional mean μ_i and the dispersion parameter σ^2 , in a generalized linear mixed-effects model is

$$\text{var}(y_i | \mu_i, \sigma^2) = \frac{\sigma^2}{w_i} v(\mu_i),$$

where w_i is the i th observation weight and v is the variance function for the specified conditional distribution of the response. The **Dispersion** property contains an estimate of σ^2 for the specified GLME model. The value of **Dispersion** depends on the specified conditional distribution of the response. For binomial and Poisson distributions, the theoretical value of **Dispersion** is equal to $\sigma^2 = 1.0$.

- If **FitMethod** is **MPL** or **REMP** and the '**DispersionFlag**' name-value pair argument in **fitglme** is **true**, then a dispersion parameter is estimated from data for all distributions, including binomial and Poisson distributions.
- If **FitMethod** is **ApproximateLaplace** or **Laplace**, then the '**DispersionFlag**' name-value pair argument in **fitglme** does not apply, and the dispersion parameter is fixed at 1.0 for binomial and Poisson distributions. For all other distributions, **Dispersion** is estimated from data.

Data Types: double

DispersionEstimated — Flag indicating if dispersion parameter was estimated

true | false

Flag indicating estimated dispersion parameter, stored as a logical value.

- If `FitMethod` is `ApproximateLaplace` or `Laplace`, then the dispersion parameter is fixed at its theoretical value of 1.0 for binomial and Poisson distributions, and `DispersionEstimated` is `false`. For other distributions, the dispersion parameter is estimated from the data, and `DispersionEstimated` is `true`.
- If `FitMethod` is `MPL` or `REMP`, and the `'DispersionFlag'` name-value pair argument in `fitglm` is specified as `true`, then the dispersion parameter is estimated for all distributions, including binomial and Poisson distributions, and `DispersionEstimated` is `true`.
- If `FitMethod` is `MPL` or `REMP`, and the `'DispersionFlag'` name-value pair argument in `fitglm` is specified as `false`, then the dispersion parameter is fixed at its theoretical value for binomial and Poisson distributions, and `DispersionEstimated` is `false`. For distributions other than binomial and Poisson, the dispersion parameter is estimated from the data, and `DispersionEstimated` is `true`.

Data Types: logical

Distribution — Response distribution name

'Normal' | 'Binomial' | 'Poisson' | 'Gamma' | 'InverseGaussian'

Response distribution name, stored as one of the following:

- `'Normal'` — Normal distribution
- `'Binomial'` — Binomial distribution
- `'Poisson'` — Poisson distribution
- `'Gamma'` — Gamma distribution
- `'InverseGaussian'` — Inverse Gaussian distribution

FitMethod — Method used to fit the model

'MPL' | 'REMP' | 'ApproximateLaplace' | 'Laplace'

Method used to fit the model, stored as one of the following.

- `'MPL'` — Maximum pseudo likelihood
- `'REMP'` — Restricted maximum pseudo likelihood

- 'ApproximateLaplace' — Maximum likelihood using the approximate Laplace method, with fixed effects profiled out
- 'Laplace' — Maximum likelihood using the Laplace method

Formula — Model specification formula

object

Model specification formula, stored as an object. The model specification formula uses Wilkinson's notation to describe the relationship between the fixed-effects terms, random-effects terms, and grouping variables in the GLME model. For more information see Formula.

Link — Link function characteristics

structure

Link function characteristics, stored as a structure containing the following fields. The link is a function G that links the distribution parameter μ to the linear predictor η as follows: $G(\mu) = \eta$.

Field	Description
Name	Name of the link function
Link	Function that defines G
Derivative	Derivative of G
SecondDerivative	Second derivative of G
Inverse	Inverse of G

Data Types: struct

LogLikelihood — Log of likelihood function

scalar value

Log of likelihood function evaluated at the estimated coefficient values, stored as a scalar value. LogLikelihood depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then LogLikelihood is the maximized log likelihood.
- If you use 'MPL', then LogLikelihood is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.

- If you use 'REML', then `LogLikelihood` is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

Data Types: double

ModelCriterion — Model criterion

table

Model criterion to compare fitted generalized linear mixed-effects models, stored as a table with the following fields.

Field	Description
AIC	Akaike information criterion
BIC	Bayesian information criterion
LogLikelihood	<ul style="list-style-type: none"> • For a model fit using 'Laplace' or 'ApproximateLaplace', <code>LogLikelihood</code> is the maximized log likelihood. • For a model fit using 'MPL', <code>LogLikelihood</code> is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration. • For a model fit using 'REML', <code>LogLikelihood</code> is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.
Deviance	-2 times <code>LogLikelihood</code>

NumCoefficients — Number of fixed-effects coefficients

positive integer value

Number of fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumEstimatedCoefficients — Number of estimated fixed-effects coefficients

positive integer value

Number of estimated fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumObservations — Number of observations

positive integer value

Number of observations used in the fit, stored as a positive integer value. `NumObservations` is the number of rows in the table or dataset array `tbl`, minus rows excluded using the 'Exclude' name-value pair of `fitglme` or rows containing NaN values.

Data Types: double

NumPredictors — Number of predictors

positive integer value

Number of variables used as predictors in the generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumVariables — Total number of variables

positive integer value

Total number of variables, including the response and predictors, stored as a positive integer value. If the sample data is in a table or dataset array `tbl`, then `NumVariables` is the total number of variables in `tbl`, including the response variable. `NumVariables` includes variables, if any, that are not used as predictors or as the response.

Data Types: double

ObservationInfo — Information about the observations

table

Information about the observations used in the fit, stored as a table.

`ObservationInfo` has one row for each observation and the following columns.

Name	Description
Weights	The weight value for the observation. The default value is 1.

Name	Description
Excluded	If the observation was excluded from the fit using the 'Exclude' name-value pair argument in <code>fitglm</code> , then <code>Excluded</code> is <code>true</code> , or 1. Otherwise, <code>Excluded</code> is <code>false</code> , or 0.
Missing	If the observation was excluded from the fit because any response or predictor value is missing, then <code>Missing</code> is <code>true</code> . Otherwise, <code>Missing</code> is <code>false</code> . Missing values include NaN for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the <code><undefined></code> value for categorical arrays.
Subset	If the observation was used in the fit, then <code>Subset</code> is <code>true</code> . If the observation was not used in the fit because it is missing or excluded, then <code>Subset</code> is <code>false</code> .
BinomSize	Binomial size for each observation. This column only applies when fitting a binomial distribution.

Data Types: table

ObservationNames — Names of observations

cell array of character vectors

Names of observations used in the fit, stored as a cell array of character vectors.

- If the data is in a table or dataset array `tbl` that contains observation names, then `ObservationNames` uses those names.
- If the data is provided in matrices, or in a table or dataset array without observation names, then `ObservationNames` is an empty cell array.

Data Types: cell

PredictorNames — Names of predictors

cell array of character vectors

Names of the variables used as predictors in the fit, stored as a cell array of character vectors that has the same length as NumPredictors.

Data Types: cell

ResponseName — Name of response variable

character vector

Name of the variable used as the response variable in the fit, stored as a character vector.

Data Types: char

Rsquared — Proportion of variability in the response explained by the fitted model

structure

Proportion of variability in the response explained by the fitted model, stored as a structure. **Rsquared** contains the *R*-squared value of the fitted model, also known as the multiple correlation coefficient. **Rsquared** contains the following fields.

Field	Description
Ordinary	R-squared value, stored as a scalar value in a structure. $\text{Rsquared.Ordinary} = 1 - \text{SSE./SST}$
Adjusted	R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure. $\text{Rsquared.Adjusted} = 1 - (\text{SSE./SST}) * (\text{DFT./DFE}),$ where $\text{DFE} = n - p$, $\text{DFT} = n - 1$, n is the total number of observations, and p is the number of fixed-effects coefficients.

Data Types: struct

SSE — Error sum of squares

positive scalar value

Error sum of squares, stored as a positive scalar value. **SSE** is the weighted sum of the squared conditional residuals, and is calculated as

$$SSE = \sum_{i=1}^n w_i^{eff} (y_i - f_i)^2,$$

where n is the number of observations, w_i^{eff} is the i th effective weight, y_i is the i th response, and f_i is the i th fitted value.

The i th effective weight is calculated as

$$w_i^{eff} = \left\{ \frac{w_i}{v_i(\mu_i(\hat{\beta}, \hat{b}))} \right\},$$

where v_i is the variance term for the i th observation, $\hat{\beta}$ and \hat{b} are estimated values of β and b , respectively.

The i th fitted value is calculated as

$$f_i = g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{b} + \delta_i),$$

where x_i^T is the i th row of the fixed-effects design matrix X , and z_i^T is the i th row of the random-effects design matrix Z . δ_i is the i th offset value.

Data Types: double

SSR — Regression sum of squares

positive scalar value

Regression sum of squares, stored as a positive scalar value. **SSR** is the sum of squares explained by the generalized linear mixed-effects regression, or equivalently the weighted sum of the squared deviations of the conditional fitted values from their weighted mean. **SSR** is calculated as

$$SSR = \sum_{i=1}^N w_i^{eff} (f_i - \bar{f})^2,$$

where n is the number of observations, w_i^{eff} is the i th effective weight, f_i is the i th fitted value, and \bar{f} is a weighted average of the fitted values.

The i th effective weight is calculated as

$$w_i^{\text{eff}} = \left\{ \frac{w_i}{v_i(\mu_i(\hat{\beta}, \hat{b}))} \right\},$$

where $\hat{\beta}$ and \hat{b} are estimated values of β and b , respectively.

The i th fitted value is calculated as

$$f_i = g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{b} + \delta_i),$$

where x_i^T is the i th row of the fixed-effects design matrix X , and z_i^T is the i th row of the random-effects design matrix Z . δ_i is the i th offset value.

The weighted average of fitted values is calculated as

$$\bar{f} = \frac{\left[\sum_{i=1}^n w_i^{\text{eff}} f_i \right]}{\sum_{i=1}^n w_i^{\text{eff}}}.$$

Data Types: double

SST — Total sum of squares

positive scalar value

Total sum of squares, stored as a positive scalar value. For a GLME model, SST is defined as $\text{SST} = \text{SSE} + \text{SSR}$.

Data Types: double

VariableInfo — Information about the variables

table

Information about the variables used in the fit, stored as a table. `VariableInfo` has one row for each variable and contains the following columns.

Column Name	Description
<code>Class</code>	Class of the variable ('double', 'cell', 'nominal', and so on).
<code>Range</code>	Value range of the variable. <ul style="list-style-type: none"> For a numerical variable, <code>Range</code> is a two-element vector of the form <code>[min,max]</code>. For a cell or categorical variable, <code>Range</code> is a cell or categorical array containing all unique values of the variable.
<code>InModel</code>	If the variable is a predictor in the fitted model, <code>InModel</code> is <code>true</code> . If the variable is not in the fitted model, <code>InModel</code> is <code>false</code> .
<code>IsCategorical</code>	If the variable type is treated as a categorical predictor (such as cell, logical, or categorical), then <code>IsCategorical</code> is <code>true</code> . If the variable is a continuous predictor, then <code>IsCategorical</code> is <code>false</code> .

Data Types: `table`

VariableNames — Names of the variables

cell array of character vectors

Names of all the variables contained in the table or dataset array `tbl`, stored as a cell array of character vectors.

Data Types: `cell`

Variables — Variables

table

Variables, stored as a table. If the fit is based on a table or dataset array `tbl`, then `Variables` is identical to `tbl`.

Data Types: `table`

Methods

<code>anova</code>	Analysis of variance for generalized linear mixed-effects model
<code>coefCI</code>	Confidence intervals for coefficients of generalized linear mixed-effects model
<code>coefTest</code>	Hypothesis test on fixed and random effects of generalized linear mixed-effects model
<code>compare</code>	Compare generalized linear mixed-effects models
<code>covarianceParameters</code>	Extract covariance parameters of generalized linear mixed-effects model
<code>designMatrix</code>	Fixed- and random-effects design matrices
<code>fitted</code>	Fitted responses from generalized linear mixed-effects model
<code>fixedEffects</code>	Estimates of fixed effects and related statistics
<code>plotResiduals</code>	Plot residuals of generalized linear mixed-effects model
<code>predict</code>	Predict response of generalized linear mixed-effects model
<code>random</code>	Generate random responses from fitted generalized linear mixed-effects model
<code>randomEffects</code>	Estimates of random effects and related statistics
<code>refit</code>	Refit generalized linear mixed-effects model
<code>residuals</code>	Residuals of fitted generalized linear mixed-effects model

response

Response vector of generalized linear mixed-effects model

Examples

Fit a Generalized Linear Mixed-Effects Model

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'mfr.mat'));
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time_dev** and **temp_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time_dev**, **temp_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as **'effects'**, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\text{log}(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company **C** or **B**, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```

Random effects coefficients	20
Covariance parameters	1
Distribution	Poisson

```

Link
FitMethod

Log
Laplace

```

Formula:

```
defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1 | factory)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
416.35	434.58	-201.17	402.35

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	1.4689	0.15988	9.1875	94	9.8194e-15
'newprocess'	-0.36766	0.17755	-2.0708	94	0.041122
'time_dev'	-0.094521	0.82849	-0.11409	94	0.90941
'temp_dev'	-0.28317	0.9617	-0.29444	94	0.76907
'supplier_C'	-0.071868	0.078024	-0.9211	94	0.35936
'supplier_B'	0.071072	0.07739	0.91836	94	0.36078

Lower	Upper
1.1515	1.7864
-0.72019	-0.015134
-1.7395	1.5505
-2.1926	1.6263
-0.22679	0.083051
-0.082588	0.22473

Random effects covariance parameters:

Group: factory (20 Levels)

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	0.31381

Group: Error

Name	Estimate
'sqrt(Dispersion)'	1

The **Model information** table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a **Poisson** distribution, the link function is **Log**, and the fit method is **Laplace**.

Formula indicates the model specification using Wilkinson's notation.

The `Model fit statistics` table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (AIC), Bayesian information criterion (BIC) values, log likelihood (`LogLikelihood`), and deviance (`Deviance`) values.

The `Fixed effects coefficients` table indicates that `fitglme` returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (`Name`) contains the name of each fixed-effects coefficient, column 2 (`Estimate`) contains its estimated value, and column 3 (`SE`) contains the standard error of the coefficient. Column 4 (`tStat`) contains the *t*-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (`DF`) and column 6 (`pValue`) contain the degrees of freedom and *P*-value that correspond to the *t*-statistic, respectively. The last two columns (`Lower` and `Upper`) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

`Random effects covariance parameters` displays a table for each grouping variable (here, only `factory`), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, `std` indicates that `fitglme` returns the standard deviation of the random effect associated with the `factory` predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by `fitglme` does not provide confidence intervals for the random-effects parameters. To compute and display these values, use `covarianceParameters`.

- “Fit a Generalized Linear Mixed-Effects Model” on page 12-77

Definitions

Formula

In general, a formula for model specification is a character vector of the form `'y ~ terms'`. For generalized linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms, respectively, and *R* is the number of grouping variables in the model.

Suppose a table `tbl` contains the following:

- A response variable, y
- Predictor variables, X_j , which can be continuous or grouping variables
- Grouping variables, g_1, g_2, \dots, g_R ,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, or cell arrays of character vectors.

Then, in a formula of the form, ' $y \sim \text{fixed} + (\text{random}_1 | g_1) + \dots + (\text{random}_R | g_R)$ ', the term `fixed` corresponds to a specification of the fixed-effects design matrix X , `random1` is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1 , and similarly `randomR` is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R . You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$)
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'.
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

GeneralizedLinearModel class

Superclasses: CompactGeneralizedLinearModel

Generalized linear regression model class

Description

An object comprising training data, model description, diagnostic information, and fitted coefficients for a generalized linear regression. Predict model responses with the `predict` or `feval` methods.

Construction

`mdl = fitglm(tbl)` or `mdl = fitglm(X,y)` creates a generalized linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`. For details, see `fitglm`.

`mdl = stepwiseglm(tbl)` or `mdl = stepwiseglm(X,y)` creates a generalized linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`, with unimportant predictors excluded. For details, see `stepwiseglm`.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-58). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double`

Properties

CoefficientCovariance — Covariance matrix of coefficient estimates

numeric matrix

Covariance matrix of coefficient estimates, stored as a p -by- p matrix of numeric values. p is the number of coefficients in the fitted model.

CoefficientNames — Coefficient names

cell array of character vectors

Coefficient names, stored as a cell array of character vectors containing a label for each coefficient.

Coefficients — Coefficient values

table

Coefficient values, stored as a table. `Coefficients` has one row for each coefficient and the following columns:

- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — t statistic for a test that the coefficient is zero
- **pValue** — p -value for the t statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

Deviance — Deviance of the fit

numeric value

Deviance of the fit, stored as a numeric value. Deviance is useful for comparing two models when one is a special case of the other. The difference between the deviance of the two models has a chi-square distribution with degrees of freedom equal to the difference in the number of estimated parameters between the two models. For more information on deviance, see “Deviance” on page 29-2801.

DFE — Degrees of freedom for error

positive integer value

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients, stored as a positive integer value.

Diagnostics — Diagnostic information

table

Diagnostic information for the model, stored as a table. Diagnostics can help identify outliers and influential observations. `Diagnostics` contains the following fields:

Field	Meaning	Utility
Leverage	Diagonal elements of <code>HatMatrix</code>	Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the

Field	Meaning	Utility
		fit is largely determined by the other observations. For a model with p coefficients and n observations, the average value of Leverage is p/n . An observation with Leverage larger than $2*p/n$ can be an outlier.
CooksDistance	Cook's measure of scaled change in fitted values	CooksDistance is a measure of scaled change in fitted values. An observation with CooksDistance larger than three times the mean Cook's distance can be an outlier.
HatMatrix	Projection matrix to compute fitted from observed responses	HatMatrix is an n -by- n matrix such that Fitted = HatMatrix * Y , where Y is the response vector and Fitted is the vector of fitted response values.

All of these quantities are computed on the scale of the linear predictor. So, for example, in the equation that defines the hat matrix,

```
Yfit = glm.Fitted.LinearPredictor
Y = glm.Fitted.LinearPredictor + glm.Residuals.LinearPredictor
```

Dispersion — Scale factor of the variance of the response

structure

Scale factor of the variance of the response, stored as a structure. **Dispersion** multiplies the variance function for the distribution.

For example, the variance function for the binomial distribution is $p(1-p)/n$, where p is the probability parameter and n is the sample size parameter. If **Dispersion** is near 1, the variance of the data appears to agree with the theoretical variance of the binomial distribution. If **Dispersion** is larger than 1, the data are “overdispersed” relative to the binomial distribution.

DispersionEstimated — Flag to indicate use of dispersion scale factor

logical value

Flag to indicate whether **fitglm** used the **Dispersion** scale factor to compute standard errors for the coefficients in **Coefficients.SE**, stored as a logical value. If **DispersionEstimated** is false, **fitglm** used the theoretical value of the variance.

- **DispersionEstimated** can be false only for 'binomial' or 'poisson' distributions.

- Set `DispersionEstimated` by setting the `DispersionFlag` name-value pair in `fitglm`.

Distribution — Generalized distribution information

structure

Generalized distribution information, stored as a structure with the following fields relating to the generalized distribution:

Field	Description
Name	Name of the distribution, one of 'normal', 'binomial', 'poisson', 'gamma', or 'inverse gamma'.
DevianceFunction	Function that computes the components of the deviance as a function of the fitted parameter values and the response values.
VarianceFunction	Function that computes the theoretical variance for the distribution as a function of the fitted parameter values. When <code>DispersionEstimated</code> is true, <code>Dispersion</code> multiplies the variance function in the computation of the coefficient standard errors.

Fitted — Fitted response values based on input data

table

Fitted (predicted) values based on the input data, stored as a table with one row for each observation and the following columns.

Field	Description
Response	Predicted values on the scale of the response.
LinearPredictor	Predicted values on the scale of the linear predictor. These are the same as the link function applied to the Response fitted values.
Probability	Fitted probabilities (this column is included only with the binomial distribution).

To obtain any of the columns as a vector, index into the property using dot notation. For example, in the model `mdl`, the vector `f` of fitted values on the response scale is

```
f = mdl.Fitted.Response
```

Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

Formula — Model information

LinearFormula object | NonLinearFormula object

Model information, stored as a LinearFormula object or NonLinearFormula object. If you fit a linear or generalized linear regression model, then Formula is a LinearFormula object. If you fit a nonlinear regression model, then Formula is a NonLinearFormula object.

Link — Link function

structure

Link function, stored as a structure with the following fields:

Field	Description
Name	Name of the link function, or ' ' if you specified the link as a function handle rather than a character vector.
LinkFunction	The function that defines f , a function handle.
DevianceFunction	Derivative of f , a function handle.
VarianceFunction	Inverse of f , a function handle.

The link is a function f that links the distribution parameter μ to the fitted linear combination Xb of the predictors:

$$f(\mu) = Xb.$$

LogLikelihood — Log likelihood

numeric value

Log likelihood of the model distribution at the response values, stored as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.

ModelCriterion — Criterion for model comparison

structure

Criterion for model comparison, stored as a structure with the following fields:

- AIC — Akaike information criterion
- AICc — Akaike information criterion corrected for sample size
- BIC — Bayesian information criterion
- CAIC — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

NumCoefficients — Number of model coefficients

positive integer

Number of model coefficients, stored as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

NumEstimatedCoefficients — Number of estimated coefficients

positive integer

Number of estimated coefficients in the model, stored as a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

NumObservations — Number of observations

positive integer

Number of observations the fitting function used in fitting, stored as a positive integer. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the `Excluded` name-value pair) or rows with missing values.

NumPredictors — Number of predictor variables

positive integer

Number of predictor variables used to fit the model, stored as a positive integer.

NumVariables — Number of variables

positive integer

Number of variables in the input data, stored as a positive integer. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

ObservationInfo — Observation information

table

Observation information, stored as a n -by-4 table, where n is equal to the number of rows of input data. The four columns of `ObservationInfo` contain the following:

Field	Description
Weights	Observation weights. Default is all 1.
Excluded	Logical value, 1 indicates an observation that you excluded from the fit with the <code>Exclude</code> name-value pair.
Missing	Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.
Subset	Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.

ObservationNames – Observation names

cell array of character vectors

Observation names, stored as a cell array of character vectors containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

Offset – Offset variable

numeric vector

Offset variable, stored as a numeric vector with the same length as the number of rows in the data. `Offset` is passed from `fitglm` or `stepwiseglm` in the `Offset` name-value pair. The fitting function used `Offset` as a predictor variable, but with the coefficient set to exactly 1. In other words, the formula for fitting was

$$\mu \sim \text{Offset} + (\text{terms involving real predictors})$$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

PredictorNames – Names of predictors used to fit the model

cell array of character vectors

Names of predictors used to fit the model, stored as a cell array of character vectors.

Residuals — Residuals for fitted model

table

Residuals for the fitted model, stored as a table with one row for each observation and the following columns.

Field	Description
Raw	Observed minus fitted values.
LinearPredictor	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors.
Pearson	Raw residuals divided by the estimated standard deviation of the response.
Anscombe	Residuals defined on transformed data with the transformation chosen to remove skewness.
Deviance	Residuals based on the contribution of each observation to the deviance.

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

ResponseName — Response variable name

character vector

Response variable name, stored as a character vector.

Rsquared — R-squared value for the model

structure

R-squared value for the model, stored as a structure.

For a linear or nonlinear model, **Rsquared** is a structure with two fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients

For a generalized linear model, **Rsquared** is a structure with five fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients
- **LLR** — Log-likelihood ratio
- **Deviance** — Deviance
- **AdjGeneralized** — Adjusted generalized R-squared

The R-squared value is the proportion of total sum of squares explained by the model.

The ordinary R-squared value relates to the **SSR** and **SST** properties:

$$\text{Rsquared} = \text{SSR}/\text{SST} = 1 - \text{SSE}/\text{SST}.$$

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

SSE — Sum of squared errors

numeric value

Sum of squared errors (residuals), stored as a numeric value.

The Pythagorean theorem implies

$$\text{SST} = \text{SSE} + \text{SSR}.$$

SSR — Regression sum of squares

numeric value

Regression sum of squares, stored as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies
 $SST = SSE + SSR$.

SST — Total sum of squares

numeric value

Total sum of squares, stored as a numeric value. The total sum of squares is equal to the sum of squared deviations of y from $\text{mean}(y)$.

The Pythagorean theorem implies
 $SST = SSE + SSR$.

Steps — Stepwise fitting information

structure

Stepwise fitting information, stored as a structure with the following fields.

Field	Description
Start	Formula representing the starting model
Lower	Formula representing the lower bound model, these terms that must remain in the model
Upper	Formula representing the upper bound model, model cannot contain more terms than Upper
Criterion	Criterion used for the stepwise algorithm, such as 'sse'
PEnter	Value of the parameter, such as 0.05
PRemove	Value of the parameter, such as 0.10
History	Table representing the steps taken in the fit

The **History** table has one row for each step including the initial fit, and the following variables (columns).

Field	Description
Action	Action taken during this step, one of: <ul style="list-style-type: none"> 'Start' — First step 'Add' — A term is added 'Remove' — A term is removed

Field	Description
TermName	<ul style="list-style-type: none"> 'Start' step: The starting model specification 'Add' or 'Remove' steps: The term moved in that step
Terms	Terms matrix (see <code>modelspec</code> of <code>fitlm</code>)
DF	Regression degrees of freedom after this step
delDF	Change in regression degrees of freedom from previous step (negative for steps that remove a term)
Deviance	Deviance (residual sum of squares) at that step
FStat	F statistic that led to this step
PValue	p -value of the F statistic

The structure is empty unless you use `stepwiselm` or `stepwiseglm` to fit the model.

VariableInfo — Information about input variables

table

Information about input variables contained in `Variables`, stored as a table with one row for each model term and the following columns.

Field	Description
Class	Character vector giving variable class, such as 'double'
Range	Cell array giving variable range: <ul style="list-style-type: none"> Continuous variable — Two-element vector [min, max], the minimum and maximum values Categorical variable — Cell array of distinct variable values
InModel	Logical vector, where <code>true</code> indicates the variable is in the model
IsCategorical	Logical vector, where <code>true</code> indicates a categorical variable

VariableNames — Names of variables used in fit

cell array of character vectors

Names of variables used in fit, stored as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.

- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

Variables — Data used to fit the model

table

Data used to fit the model, stored as a table. `Variables` contains both observation and response values. If the fit is based on a table or dataset array, `Variables` contains all of the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix X and response vector y .

Methods

<code>addTerms</code>	Add terms to generalized linear model
<code>compact</code>	Compact generalized linear regression model
<code>fit</code>	Create generalized linear regression model
<code>plotDiagnostics</code>	Plot diagnostics of generalized linear regression model
<code>plotResiduals</code>	Plot residuals of generalized linear regression model
<code>removeTerms</code>	Remove terms from generalized linear model
<code>step</code>	Improve generalized linear regression model by adding or removing terms
<code>stepwise</code>	Create generalized linear regression model by stepwise regression

Inherited Methods

<code>coefCI</code>	Confidence intervals of coefficient estimates of generalized linear model
<code>coefTest</code>	Linear hypothesis test on generalized linear regression model coefficients

devianceTest	Analysis of deviance
disp	Display generalized linear regression model
feval	Evaluate generalized linear regression model prediction
plotSlice	Plot of slices through fitted generalized linear regression surface
predict	Predict response of generalized linear regression model
random	Simulate responses for generalized linear regression model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB) in the MATLAB documentation.

Examples

Fit a Generalized Linear Model

Fit a logistic regression model of probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the `hospital` dataset array.

```
load hospital
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```
mdl = fitglm(ds,modelspec,'Distribution','binomial')
```

```
mdl =
```

```
Generalized linear regression model:
  logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
  Distribution = Binomial
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

```
100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535
```

The large *P*-value indicates the model might not differ statistically from a constant.

Create a Generalized Linear Model Stepwise

Create response data using just three of 20 predictors, and create a generalized linear model stepwise to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng default % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = stepwiseglm(X,y,...
  'constant', 'upper', 'linear', 'Distribution', 'poisson')
```

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

```
mdl =
```

```
Generalized linear regression model:
```

```
log(y) ~ 1 + x5 + x10 + x15
```

```
Distribution = Poisson
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	1.0115	0.064275	15.737	8.4217e-56
x5	0.39508	0.066665	5.9263	3.0977e-09

Definitions

Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Hat Matrix

The *hat matrix* H is defined in terms of the data matrix X and a diagonal weight matrix W :

$$H = X(X^T W X)^{-1} X^T W^T.$$

W has diagonal elements w_i :

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},$$

where

- g is the link function mapping y_i to $x_i b$.
- g' is the derivative of the link function g .
- V is the variance function.
- μ_i is the i th mean.

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the i th diagonal term, h_{ii} , of the hat matrix H . Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = w_i \frac{e_i^2}{p\hat{\phi}} \frac{h_{ii}}{(1-h_{ii})^2},$$

where

- $\hat{\phi}$ is the dispersion parameter (estimated or theoretical).
- e_i is the linear predictor residual, $g(y_i) - x_i\hat{\beta}$, where
 - g is the link function.
 - y_i is the observed response.
 - x_i is the observation.
 - $\hat{\beta}$ is the estimated coefficient vector.
- p is the number of coefficients in the regression model.
- h_{ii} is the i th diagonal element of the Hat Matrix H .

Deviance

Deviance of a model M_1 is twice the difference between the loglikelihood of that model and the saturated model, M_S . The saturated model is the model with the maximum number of parameters that can be estimated. For example, if there are n observations y_i , $i = 1, 2, \dots, n$, with potentially different values for $X_i^T\beta$, then you can define a saturated model with n parameters. Let $L(b,y)$ denote the maximum value of the likelihood function for a model. Then the deviance of model M_1 is

$$-2(\log L(b_1, y) - \log L(b_S, y)),$$

where b_1 are the estimated parameters for model M_1 and b_S are the estimated parameters for the saturated model. The deviance has a chi-square distribution with $n - p$ degrees of freedom, where n is the number of parameters in the saturated model and p is the number of parameters in model M_1 .

If M_1 and M_2 are two different generalized linear models, then the fit of the models can be assessed by comparing the deviances D_1 and D_2 of these models. The difference of the deviances is

$$\begin{aligned} D = D_2 - D_1 &= -2(\log L(b_2, y) - \log L(b_S, y)) + 2(\log L(b_1, y) - \log L(b_S, y)) \\ &= -2(\log L(b_2, y) - \log L(b_1, y)). \end{aligned}$$

Asymptotically, this difference has a chi-square distribution with degrees of freedom v equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in M_1 and M_2 . You can get the p -value for this test using `1 - chi2cdf(D, V)`, where $D = D_2 - D_1$.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `predict` and `random` methods support code generation.
- When fitting the model using `fitglm`, you cannot supply a table of data containing any categorical variables or specify categorical variables using the `CategoricalVars` name-value pair argument. That is, the `IsCategorical` variable of the `VariableInfo` property cannot contain any 'categorical' entries. To dummy-code variables that you want treated as categorical, preprocess the categorical data before fitting the model using `dummyvar`.
- The `Link`, `Derivative`, and `Inverse` fields of the `Link` name-value pair argument cannot be anonymous functions. That is, you cannot generate code using a generalized linear model that was created using anonymous functions for links. Instead, declare functions for link components.

prob.GeneralizedParetoDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Generalized Pareto probability distribution object

Description

`prob.GeneralizedParetoDistribution` is an object consisting of parameters, a model description, and sample data for a generalized Pareto probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitter app.

Construction

`pd = makedist('GeneralizedPareto')` creates a generalized Pareto probability distribution object using default parameter values.

`pd = makedist('GeneralizedPareto','k',k,'sigma',sigma,'theta',theta)` creates a generalized Pareto probability distribution object using the specified parameter values.

Input Arguments

k — Shape parameter

1 (default) | scalar value

Shape parameter for the generalized Pareto distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the generalized Pareto distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

theta — Location parameter

1 (default) | scalar value

Location parameter for the generalized Pareto distribution, specified as a scalar value.

Data Types: `single` | `double`

Properties

k — Shape parameter

scalar value

Shape parameter for the generalized Pareto distribution, stored as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter for the generalized Pareto distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

theta — Location parameter

scalar value

Location parameter for the generalized Pareto distribution, stored as a scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

character vector

Probability distribution name, stored as a character vector. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If **IsTruncated** equals 0, the distribution is not truncated. If **IsTruncated** equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

Distribution parameter descriptions, stored as a cell array of character vectors. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: logical

ParameterNames — Distribution parameter names

cell array of character vectors

Distribution parameter names, stored as a cell array of character vectors. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

`cdf`

Cumulative distribution function of probability distribution object

icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object

Examples

Create a Generalized Pareto Distribution Object Using Default Parameters

Create a generalized Pareto distribution object using the default parameter values.

```
pd = makedist('GeneralizedPareto')
```

```
pd =
```

```
GeneralizedParetoDistribution
```

```
Generalized Pareto distribution  
k = 1
```

```
sigma = 1  
theta = 1
```

Create a Generalized Pareto Distribution Object Using Specified Parameters

Create a generalized Pareto distribution object by specifying parameter values.

```
pd = makedist('GeneralizedPareto','k',0,'sigma',2,'theta',1)
```

```
pd =  
  
GeneralizedParetoDistribution  
  
Generalized Pareto distribution  
    k = 0  
    sigma = 2  
    theta = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =  
  
    3
```

Definitions

Generalized Pareto Distribution

The generalized Pareto distribution is used to model the tails of another distribution. It allows a continuous range of possible shapes that include both the exponential and Pareto distributions as special cases. It has three basic forms, each corresponding to a limiting distribution of exceedence data from a different class of underlying distributions.

- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.

- Distributions whose tails decrease polynomially, such as the Student's t , lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution uses the following parameters.

Parameter	Description	Support
k	Shape parameter	$-\infty < k < \infty$
σ	Scale parameter	$\sigma \geq 0$
θ	Location parameter	$-\infty < \theta < \infty$

The probability density function (pdf) of the generalized Pareto distribution with shape parameter $k \neq 0$ is

$$f(x | k, \sigma, \theta) = \left(\frac{1}{\sigma}\right) \left(1 + k \frac{(x - \theta)}{\sigma}\right)^{-1 - \frac{1}{k}}$$

for $x > \theta$, when $k > 0$, or for $\theta < x < -\frac{\sigma}{k}$, when $k < 0$.

For $k = 0$, the pdf is

$$y = f(x | 0, \sigma, \theta) = \left(\frac{1}{\sigma}\right) \exp\left(-\frac{(x - \theta)}{\sigma}\right)$$

for $x > \theta$.

If $k = 0$ and $\theta = 0$, the generalized Pareto distribution is equivalent to the exponential

distribution. If $k > 0$ and $\theta = \frac{\sigma}{k}$, the generalized Pareto distribution is equivalent to the Pareto distribution.

Class Attributes (MATLAB)

Property Attributes (MATLAB)

geocdf

Geometric cumulative distribution function

Syntax

```
y = geocdf(x,p)
y = geocdf(x,p,'upper')
```

Description

`y = geocdf(x,p)` returns the cumulative distribution function (cdf) of the geometric distribution at each value in `x` using the corresponding probabilities in `p`. `x` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `p` must lie on the interval `[0,1]`.

`y = geocdf(x,p,'upper')` returns the complement of the geometric distribution cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Geometric Distribution cdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing three or fewer tails ("failures") before tossing a heads?

To solve, determine the value of the cumulative distribution function (cdf) for the geometric distribution at `x` equal to 3. The probability of success (tossing a heads) `p` in any given trial is 0.5.

```
x = 3;
p = 0.5;
y = geocdf(x,p)
```

`y =`

`0.9375`

The returned value of `y` indicates that the probability of observing three or fewer tails before tossing a heads is 0.9375.

Definitions

Geometric Distribution cdf

The cumulative distribution function (cdf) of the geometric distribution is

$$y = F(x | p) = 1 - (1 - p)^{x+1}; x = 0, 1, 2, \dots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing up to x trials before a success, when the probability of success in any given trial is p .

Extended Capabilities

Topics

“Geometric Distribution” on page B-63

Introduced before R2006a

geoinv

Geometric inverse cumulative distribution function

Syntax

```
x = geoinv(y,p)
```

Description

`x = geoinv(y,p)` returns the inverse cumulative distribution function (icdf) of the geometric distribution at each value in `y` using the corresponding probabilities in `p`.

`geoinv` returns the smallest positive integer `x` such that the geometric cdf evaluated at `x` is equal to or exceeds `y`. You can think of `y` as the probability of observing `x` successes in a row in independent trials, where `p` is the probability of success in each trial.

`y` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `p` or `y` is expanded to a constant array with the same dimensions as the other input. The values in `p` and `y` must lie on the interval `[0, 1]`.

Examples

Compute Geometric Distribution icdf

Suppose the probability of a five-year-old car battery not starting in cold weather is 0.03. If we want no more than a ten percent chance that the car does not start, what is the maximum number of days in a row that we should try to start the car?

To solve, compute the inverse cdf of the geometric distribution. In this example, a "success" means the car does not start, while a "failure" means the car does start. The probability of success for each trial `p` equals 0.03, while the probability of observing `x` failures in a row before observing a success `y` equals 0.1.

```
y = 0.1;  
p = 0.03;  
x = geoinv(y,p)
```

```
x =  
    3
```

The returned result indicates that if we start the car three times, there is at least a ten percent chance that it will not start on one of those tries. Therefore, if we want no greater than a ten percent chance that the car will not start, we should only attempt to start it for a maximum of two days in a row.

We can confirm this result by evaluating the cdf at values of x equal to 2 and 3, given the probability of success for each trial p equal to 0.03.

```
y2 = geocdf(2,p) % cdf for x = 2  
y3 = geocdf(3,p) % cdf for x = 3
```

```
y2 =  
    0.0873
```

```
y3 =  
    0.1147
```

The returned results indicate an 8.7% chance of the car not starting if we try two days in a row, and an 11.5% chance of not starting if we try three days in a row.

geomean

Geometric mean

Syntax

```
m = geomean(x)
geomean(X,dim)
```

Description

`m = geomean(x)` calculates the geometric mean of a sample. For vectors, `geomean(x)` is the geometric mean of the elements in `x`. For matrices, `geomean(X)` is a row vector containing the geometric means of each column. For N-dimensional arrays, `geomean` operates along the first nonsingleton dimension of `X`.

`geomean(X,dim)` takes the geometric mean along the dimension `dim` of `X`.

The geometric mean is

$$m = \left[\prod_{i=1}^n x_i \right]^{\frac{1}{n}}$$

Examples

The arithmetic mean is greater than or equal to the geometric mean.

```
x = exprnd(1,10,6);
```

```
geometric = geomean(x)
```

```
geometric =
```

```
0.7466 0.6061 0.6038 0.2569 0.7539 0.3478
```

```
average = mean(x)
```

```
average =
```

Introduced before R2006a

geopdf

Geometric probability density function

Syntax

```
y = geopdf(x,p)
```

Description

`y = geopdf(x,p)` returns the probability density function (pdf) of the geometric distribution at each value in `x` using the corresponding probabilities in `p`. `x` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `p` must lie on the interval `[0, 1]`.

Examples

Compute Geometric Distribution pdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing exactly three tails ("failures") before tossing a heads?

To solve, determine the value of the probability density function (pdf) for the geometric distributon at `x` equal to 3. The probability of success (tossing a heads) `p` in any given trial is 0.5.

```
x = 3;  
p = 0.5;  
y = geopdf(x,p)
```

```
y =
```

```
0.0625
```

The returned value of y indicates that the probability of observing exactly three tails before tossing a heads is 0.0625.

Definitions

Geometric Distribution pdf

The probability distribution function (pdf) of the geometric distribution is

$$y = f(x | p) = p(1 - p)^x \quad ; \quad x = 0, 1, 2, \dots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing exactly x trials before a success, when the probability of success in any given trial is p . For discrete distributions, the probability distribution function is also known as the probability mass function (pmf).

Topics

“Geometric Distribution” on page B-63

Introduced before R2006a

geornd

Geometric random numbers

Syntax

```
r = geornd(p)
r = geornd(p,m,n,...)
r = geornd(p,[m,n,...])
```

Description

`r = geornd(p)` generates random numbers from a geometric distribution with probability parameter `p`. `p` can be a vector, a matrix, or a multidimensional array. The size of `r` is equal to the size of `p`. The parameters in `p` must lie in the interval `[0,1]`.

`r = geornd(p,m,n,...)` or `r = geornd(p,[m,n,...])` generates a multidimensional `m`-by-`n`-by-... array containing random numbers from the geometric distribution with probability parameter `p`. `p` can be a scalar or an array of the same size as `r`.

The geometric distribution is useful to model the number of failures before one success in a series of independent trials, where each trial results in either success or failure, and the probability of success in any individual trial is the constant `p`.

Examples

Generate Random Numbers from Geometric Distribution

Generate a single random number from a geometric distribution with probability parameter `p` equal to 0.01.

```
rng default % For reproducibility
p = 0.01;
r1 = geornd(0.01)
```

```
r1 =  
    20
```

The returned random number represents a single experiment in which 20 failures were observed before a success, where each independent trial has a probability of success p equal to 0.01.

Generate a 1-by-5 array of random numbers from a geometric distribution with probability parameter p equal to 0.01.

```
r2 = geornd(p,1,5)  
  
r2 =  
     9    205     9    45    231
```

Each random number in the returned array represents the result of an experiment to determine the number of failures observed before a success, where each independent trial has a probability of success p equal to 0.01.

Generate a 1-by-3 array containing one random number from each of the three geometric distributions corresponding to the parameters in the 1-by-3 array of probabilities p .

```
p = [0.01 0.1 0.5];  
r3 = geornd(p,[1 3])
```

```
r3 =  
    127     5     0
```

Each element of the returned 1-by-3 array `r3` contains one random number generated from the geometric distribution described by the corresponding parameter in `P`. For example, the first element in `r3` represents an experiment in which 127 failures were observed before a success, where each independent trial has a probability of success p equal to 0.01. The second element in `r3` represents an experiment in which 5 failures were observed before a success, where each independent trial has a probability of success p equal to 0.1. The third element in `r3` represents an experiment in which zero failures

were observed before a success - in other words, the first attempt was a success - where each independent trial has a probability of success p equal to 0.5.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

Topics

“Geometric Distribution” on page B-63

Introduced before R2006a

geostat

Geometric mean and variance

Syntax

```
[m,v] = geostat(p)
```

Description

`[m,v] = geostat(p)` returns the mean `m` and variance `v` of a geometric distribution with corresponding probability parameters in `p`. `p` can be a vector, a matrix, or a multidimensional array. The parameters in `p` must lie in the interval `[0,1]`.

Examples

Compute Mean and Variance of Geometric Distribution

Define a probability vector that contains six different parameter values.

```
p = 1./(1:6)
```

```
p =
```

```
    1.0000    0.5000    0.3333    0.2500    0.2000    0.1667
```

Compute the mean and variance of the geometric distribution that corresponds to each value contained in probability vector.

```
[m,v] = geostat(1./(1:6))
```

```
m =
```

```
    0    1.0000    2.0000    3.0000    4.0000    5.0000
```

v =

0 2.0000 6.0000 12.0000 20.0000 30.0000

The returned values indicate that, for example, the mean of a geometric distribution with probability parameter p equal to 1/3 is 2, and its variance is 6.

Definitions

Geometric Distribution Mean and Variance

The mean of the geometric distribution is

$$\text{mean} = \frac{1-p}{p},$$

and the variance of the geometric distribution is

$$\text{var} = \frac{1-p}{p^2},$$

where p is the probability of success.

clustering.evaluation.GapEvaluation class

Package: clustering.evaluation

Superclasses: clustering.evaluation.ClusterCriterion

Gap criterion clustering evaluation object

Description

`clustering.evaluation.GapEvaluation` is an object consisting of sample data, clustering data, and gap criterion values used to evaluate the optimal number of clusters. Create a gap criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x, clust, 'Gap')` creates a gap criterion clustering evaluation object.

`eva = evalclusters(x, clust, 'Gap', Name, Value)` creates a gap criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an N -by- P matrix. N is the number of observations, and P is the number of variables.

Data Types: single | double

clust — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in <code>x</code> using the <code>kmeans</code> clustering algorithm, with <code>'EmptyAction'</code> set to <code>'singleton'</code> and <code>'Replicates'</code> set to 5.
'linkage'	Cluster the data in <code>x</code> using the <code>clusterdata</code> agglomerative clustering algorithm, with <code>'Linkage'</code> set to <code>'ward'</code> .
'gmdistribution'	Cluster the data in <code>x</code> using the <code>gmdistribution</code> Gaussian mixture distribution algorithm, with <code>'SharedCov'</code> set to <code>true</code> and <code>'Replicates'</code> set to 5.

If `Criterion` is `'CalinskHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form `C = clustfun(DATA,K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric n -by- K matrix of score for n observations and K classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `Criterion` is `'CalinskHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can also specify `clust` as a n -by- K matrix containing the proposed clustering solutions. n is the number of observations in the sample data, and K is the number of proposed clustering solutions. Column j contains the cluster indices for each of the N points in the j th clustering solution.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'KList',[1:5],'Distance','cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the sum of absolute differences distance measure.

'B' — Number of reference data sets

100 (default) | positive integer value

Number of reference data sets generated from the reference distribution `ReferenceDistribution`, specified as the comma-separated pair consisting of `'B'` and a positive integer value.

Example: `'B',150`

'Distance' — Distance metric

`'sqEuclidean'` (default) | `'Euclidean'` | `'cityblock'` | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of `'Distance'` and one of the following.

<code>'sqEuclidean'</code>	Squared Euclidean distance
<code>'Euclidean'</code>	Euclidean distance
<code>'cityblock'</code>	Sum of absolute differences
<code>'cosine'</code>	One minus the cosine of the included angle between points (treated as vectors)
<code>'correlation'</code>	One minus the sample correlation between points (treated as sequences of values)

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using a function handle (MATLAB). The distance function must be of the form

```
d2 = distfun(XI,XJ),
```

where `XI` is a 1-by- n vector corresponding to a single row of the input matrix `X`, and `XJ` is an m_2 -by- n matrix corresponding to multiple rows of `X`. `distfun` must return an m_2 -by-1 vector of distances `d2`, whose k th element is the distance between `XI` and `XJ(k,:)`.

If `Criterion` is `'silhouette'`, you can also specify `Distance` as the output vector output created by the function `pdist`.

When `Clust` a character vector representing a built-in clustering algorithm, `evalclusters` uses the distance metric specified for `Distance` to cluster the data, except for the following:

- If `Clust` is `'linkage'`, and `Distance` is either `'sqEuclidean'` or `'Euclidean'`, then the clustering algorithm uses Euclidean distance and Ward linkage.

- If `Clust` is `'linkage'` and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.

In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: `'Distance', 'Euclidean'`

'KList' — List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of `'KList'` and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name or a function handle. When `criterion` is `'gap'`, `clust` must be a character vector or a function handle, and you must specify `KList`.

Example: `'KList', [1:6]`

'ReferenceDistribution' — Reference data generation method

`'PCA'` (default) | `'uniform'`

Reference data generation method, specified as the comma-separated pair consisting of `'ReferenceDistributions'` and one of the following.

<code>'PCA'</code>	Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix <code>x</code> .
<code>'uniform'</code>	Generate reference data uniformly over the range of each feature in the data matrix <code>x</code> .

Example: `'ReferenceDistribution', 'uniform'`

'SearchMethod' — Method for selecting optimal number of clusters

`'globalMaxSE'` (default) | `'firstMaxSE'`

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of `'SearchMethod'` and one of the following.

<code>'globalMaxSE'</code>	Evaluate each proposed number of clusters in <code>KList</code> and select the smallest number of clusters satisfying
----------------------------	---

$$\text{Gap}(K) \geq \text{GAPMAX} - \text{SE}(\text{GAPMAX}),$$

where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, GAPMAX is the largest gap value, and $\text{SE}(\text{GAPMAX})$ is the standard error corresponding to the largest gap value.

'firstMaxSE'

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1),$$

where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, and $\text{SE}(K + 1)$ is the standard error of the clustering solution with $K + 1$ clusters.

Example: 'SearchMethod', 'globalMaxSE'

Properties

B

Number of data sets generated from the reference distribution, stored as a positive integer value.

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

CriterionValues

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

Distance

Distance measure used for clustering data, stored as a valid distance measure name.

ExpectedLogW

Expectation of the natural logarithm of W based on the generated reference data, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance measurement `Distance`.

InspectedK

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

LogW

Natural logarithm of W based on the input data, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance measurement `Distance`.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix X is not used in the clustering solution.

NumObservations

Number of observations in the data matrix X , minus the number of missing (NaN) values in X , stored as a positive integer value.

OptimalK

Optimal number of clusters, stored as a positive integer value.

OptimalY

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

ReferenceDistribution

Reference data generation method, stored as a valid reference distribution name.

SE

Standard error of the natural logarithm of W with respect to the reference data for each number of clusters in `InspectedK`, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance measurement `Distance`.

SearchMethod

Method for determining the optimal number of clusters, stored as a valid search method name.

StdLogW

Standard deviation of the natural logarithm of W with respect to the reference data for each number of clusters in `InspectedK`. W is the within-cluster dispersion computed using the distance measurement `Distance`.

X

Data used for clustering, stored as a matrix of numerical values.

Methods

`increaseB` Increase reference data sets

Inherited Methods

`addK` Evaluate additional numbers of clusters
`plot` Plot clustering evaluation object criterion values
`compact` Compact clustering evaluation object

Examples**Evaluate the Clustering Solution Using Gap Criterion**

Evaluate the optimal number of clusters using the gap clustering evaluation criterion.

Load the sample data.

```
load fisheriris
```

The data contains sepal and petal measurements from three species of iris flowers.

Evaluate the number of clusters based on the gap criterion values. Cluster the data using `kmeans`.

```
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','gap','KList',[1:6])
```

```
eva =
```

```
GapEvaluation with properties:
```

```
NumObservations: 150
InspectedK: [1 2 3 4 5 6]
CriterionValues: [0.0720 0.5928 0.8762 1.0114 1.0534 1.0720]
OptimalK: 5
```

The `OptimalK` value indicates that, based on the gap criterion, the optimal number of clusters is four.

Plot the gap criterion values for each number of clusters tested.

```
plot(eva)
```

Based on the plot, the maximum value of the gap criterion occurs at five clusters. However, the value at four clusters is within one standard error of the maximum, so the suggested optimal number of clusters is four.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```
figure
PetalLength = meas(:,3);
PetalWidth = meas(:,4);
ClusterGroup = eva.OptimalY;
gscatter(PetalLength,PetalWidth,ClusterGroup,'rbgk','xod^')
```

The plot shows cluster 1 in the lower-left corner, completely separated from the other three clusters. Cluster 1 contains flowers with the smallest petal widths and lengths. Cluster 4 is in the upper-right corner, and contains flowers with the largest petal widths

and lengths. Clusters 2 and 3 are near the center of the plot, and contain flowers with measurements between the two extremes.

Definitions

Gap Value

A common graphical approach to cluster evaluation involves plotting an error measurement versus several proposed numbers of clusters, and locating the “elbow” of this plot. The “elbow” occurs at the most dramatic decrease in error measurement. The gap criterion formalizes this approach by estimating the “elbow” location as the number of clusters with the largest gap value. Therefore, under the gap criterion, the optimal number of clusters occurs at the solution with the largest local or global gap value within a tolerance range.

The gap value is defined as

$$Gap_n(k) = E_n^* \{ \log(W_k) \} - \log(W_k),$$

where n is the sample size, k is the number of clusters being evaluated, and W_k is the pooled within-cluster dispersion measurement

$$W_k = \sum_{r=1}^k \frac{1}{2n_r} D_r,$$

where n_r is the number of data points in cluster r , and D_r is the sum of the pairwise distances for all points in cluster r .

The expected value $E_n^* \{ \log(W_k) \}$ is determined by Monte Carlo sampling from a reference distribution, and $\log(W_k)$ is computed from the sample data.

The gap value is defined even for clustering solutions that contain only one cluster, and can be used with any distance metric. However, the gap criterion is more computationally expensive than other cluster evaluation criteria, because the clustering algorithm must be applied to the reference data for each proposed clustering solution.

Topics

Class Attributes (MATLAB)
Property Attributes (MATLAB)

get

Class: dataset

Access dataset array properties

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
get(A)
s = get(A)
p = get(A,PropertyName)
p = get(A,{PropertyName1,PropertyName2,...})
```

Description

`get(A)` displays a list of property/value pairs for the dataset array `A`.

`s = get(A)` returns the values in a scalar structure `s` with field names given by the properties.

`p = get(A,PropertyName)` returns the value of the property specified by `PropertyName`.

`p = get(A,{PropertyName1,PropertyName2,...})` allows multiple property names to be specified and returns their values in a cell array.

Examples

Create a dataset array from Fisher's iris data and access the information.

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
              {meas,'SL','SW','PL','PW'},...
              'ObsNames',NameObs);

get(iris)
  Description: ''
  Units: {}
  DimNames: {'Observations' 'Variables'}
  UserData: []
  ObsNames: {150x1 cell}
  VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}

ON = get(iris,'ObsNames');
ON(1:3)
ans =
  'Obs1'
  'Obs2'
  'Obs3'
```

See Also

[set](#) | [summary](#)

getlabels

Access categorical array labels

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
labels = getlabels(A)
```

Description

`labels = getlabels(A)` returns the labels of the levels in the nominal or ordinal array `A` as a cell array of character vectors, `labels`. If `A` is an ordinal array, `getlabels` returns the labels in the order of the levels.

Examples

- “Change Category Labels” on page 2-10

Input Arguments

A — **Nominal or ordinal array**
nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

getlevels

Access categorical array levels

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
L = getlevels(A)
```

Description

`L = getlevels(A)` returns the levels in the nominal or ordinal array `A` in `L`, a vector with the same type as `A`.

Examples

- “Add and Drop Category Levels” on page 2-25
- “Merge Category Levels” on page 2-22
- “Reorder Category Levels” on page 2-12

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

gevcdf

Generalized extreme value cumulative distribution function

Syntax

```
p = gevcdf(x,k,sigma,mu)
p = gevcdf(x,k,sigma,mu, 'upper')
```

Description

`p = gevcdf(x,k,sigma,mu)` returns the cdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

`p = gevcdf(x,k,sigma,mu, 'upper')` returns the complement of the cdf of the GEV distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblcdf` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evcdf` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-mu)/sigma > -1$.

Topics

“Generalized Extreme Value Distribution” on page B-53

Introduced before R2006a

gevfit

Generalized extreme value parameter estimates

Syntax

```
parmhat = gevfit(X)
[parmhat,parmci] = gevfit(X)
[parmhat,parmci] = gevfit(X,alpha)
[...] = gevfit(X,alpha,options)
```

Description

`parmhat = gevfit(X)` returns maximum likelihood estimates of the parameters for the generalized extreme value (GEV) distribution given the data in `X`. `parmhat(1)` is the shape parameter, `k`, `parmhat(2)` is the scale parameter, `sigma`, and `parmhat(3)` is the location parameter, `mu`.

`[parmhat,parmci] = gevfit(X)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gevfit(X,alpha)` returns $100(1-\text{alpha})\%$ confidence intervals for the parameter estimates.

`[...] = gevfit(X,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gevfit')` for parameter names and default values. Pass in `[]` for `alpha` to use the default values.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblfit` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evfit` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution is defined for $k*(X-\text{mu})/\text{sigma} > -1$.

Introduced before R2006a

gevinv

Generalized extreme value inverse cumulative distribution function

Syntax

```
X = gevinv(P,k,sigma,mu)
```

Description

`X = gevinv(P,k,sigma,mu)` returns the inverse cdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter `mu`, evaluated at the values in `P`. The size of `X` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblinv` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evinv` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

gevlike

Generalized extreme value negative log-likelihood

Syntax

```
nlogL = gevlike(params,data)
[nlogL,ACOV] = gevlike(params,data)
```

Description

`nlogL = gevlike(params,data)` returns the negative of the log-likelihood `nlogL` for the generalized extreme value (GEV) distribution, evaluated at parameters `params`. `params(1)` is the shape parameter, `k`, `params(2)` is the scale parameter, `sigma`, and `params(3)` is the location parameter, `mu`.

`[nlogL,ACOV] = gevlike(params,data)` returns the inverse of Fisher's information matrix, `ACOV`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `ACOV` are their asymptotic variances. `ACOV` is based on the observed Fisher's information, not the expected information.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wbllike` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evlike` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

gevpdf

Generalized extreme value probability density function

Syntax

$Y = \text{gevpdf}(X, k, \text{sigma}, \mu)$

Description

$Y = \text{gevpdf}(X, k, \text{sigma}, \mu)$ returns the pdf of the generalized extreme value (GEV) distribution with shape parameter k , scale parameter sigma , and location parameter, μ , evaluated at the values in X . The size of Y is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for k , sigma , and μ are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblpdf` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evcdf` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\text{sigma} > -1$.

Topics

“Generalized Extreme Value Distribution” on page B-53

Introduced before R2006a

gevrnd

Generalized extreme value random numbers

Syntax

```
R = gevrnd(k,sigma,mu)
R = gevrnd(k,sigma,mu,m,n,...)
R = gevrnd(k,sigma,mu,[m,n,...])
```

Description

`R = gevrnd(k,sigma,mu)` returns an array of random numbers chosen from the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`. The size of `R` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `R` is the size of the other parameters.

`R = gevrnd(k,sigma,mu,m,n,...)` or `R = gevrnd(k,sigma,mu,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the GEV distribution with parameters `k`, `sigma`, and `mu`. The `k`, `sigma`, `mu` parameters can each be scalars or arrays of the same size as `R`.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblrnd` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evrnd` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

gevstat

Generalized extreme value mean and variance

Syntax

`[M,V] = gevstat(k,sigma,mu)`

Description

`[M,V] = gevstat(k,sigma,mu)` returns the mean of and variance for the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`. The sizes of `M` and `V` are the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblstat` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evstat` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

gline

Interactively add line to plot

Syntax

```
gline(h)
gline
hline = gline(...)
```

Description

`gline(h)` allows you to draw a line segment in the figure with handle `h` by clicking the pointer at the two endpoints. A rubber-band line tracks the pointer movement.

`gline` with no input arguments defaults to `h = gcf` and draws in the current figure.

`hline = gline(...)` returns the handle `hline` to the line.

Examples

Use `gline` to connect two points in a plot:

```
x = 1:10;

y = x + randn(1,10);
scatter(x,y,25,'b','*')

lsline

mu = mean(y);
hold on
plot([1 10],[mu mu],'ro')

hline = gline; % Connect circles
set(hline,'Color','r')
```

`refline` | `refcurve` | `lsline`

Introduced before R2006a

glmfit

Generalized linear model regression

Syntax

```
b = glmfit(X,y,distr)
b = glmfit(X,y,distr,param1,val1,param2,val2,...)
[b,dev] = glmfit(...)
[b,dev,stats] = glmfit(...)
```

Description

`b = glmfit(X,y,distr)` returns a $(p + 1)$ -by-1 vector **b** of coefficient estimates for a generalized linear regression of the responses in **y** on the predictors in **X**, using the distribution *distr*. **X** is an n -by- p matrix of p predictors at each of n observations. *distr* can be any of the following: 'binomial', 'gamma', 'inverse gaussian', 'normal' (the default), and 'poisson'.

In most cases, **y** is an n -by-1 vector of observed responses. For the binomial distribution, **y** can be a binary vector indicating success or failure at each observation, or a two column matrix with the first column indicating the number of successes for each observation and the second column indicating the number of trials for each observation.

This syntax uses the canonical link (see below) to relate the distribution to the predictors.

Note: By default, `glmfit` adds a first column of 1s to **X**, corresponding to a constant term in the model. Do not enter a column of 1s directly into **X**. You can change the default behavior of `glmfit` using the 'constant' parameter, below.

`glmfit` treats NaNs in either **X** or **y** as missing values, and ignores them.

`b = glmfit(X,y,distr,param1,val1,param2,val2,...)` additionally allows you to specify optional parameter name/value pairs to control the model fit. Acceptable parameters are as follows.

Parameter	Value	Description
'link'	'identity', default for the distribution 'normal'	$\mu = Xb$
	'log', default for the distribution 'poisson'	$\log(\mu) = Xb$
	'logit', default for the distribution 'binomial'	$\log(\mu/(1 - \mu)) = Xb$
	'probit'	$\text{norminv}(\mu) = Xb$
	'comploglog'	$\log(-\log(1 - \mu)) = Xb$
	'reciprocal', default for the distribution 'gamma'	$1/\mu = Xb$
	'loglog'	$\log(-\log(\mu)) = Xb$
	p (a number), default for the distribution 'inverse gaussian' (with $p = -2$)	$\mu^p = Xb$
cell array of the form {FL FD FI}, containing three function handles, created using @, that define the link (FL), the derivative of the link (FD), and the inverse link (FI).	<p>Custom-defined link function. You must provide</p> <ul style="list-style-type: none"> • FL(mu) • FD = dFL(mu) / dmu • FI = FL^(-1) 	

Parameter	Value	Description
	structure array having these fields: <ul style="list-style-type: none"> • 'Link' — Link function • 'Derivative' — Derivative of the link function • 'Inverse' — Inverse of the link function The value of each field is a character vector corresponding to a function that is on the path or a function handle (created using @).	Custom-defined link function, its derivative, and its inverse.
'estdisp'	'on'	Estimates a dispersion parameter for the binomial or Poisson distribution.
	'off' (Default for binomial or Poisson distribution)	Uses the theoretical value of 1.0 for those distributions.
'offset'	Vector	Used as an additional predictor variable, but with a coefficient value fixed at 1.0.
'weights'	Vector of prior weights, such as the inverses of the relative variance of each observation	
'constant'	'on' (default)	Includes a constant term in the model. The coefficient of the constant term is the first element of b .
	'off'	Omit the constant term.

`[b,dev] = glmfit(...)` returns `dev`, the deviance of the fit at the solution vector. The deviance is a generalization of the residual sum of squares. It is possible to perform an analysis of deviance to compare several models, each a subset of the other, and to test

whether the model with more terms is significantly better than the model with fewer terms.

`[b,dev,stats] = glmfit(...)` returns `dev` and `stats`.

`stats` is a structure with the following fields:

- `beta` — Coefficient estimates `b`
- `dfe` — Degrees of freedom for error
- `sfit` — Estimated dispersion parameter
- `s` — Theoretical or estimated dispersion parameter
- `estdisp` — 0 when the `'estdisp'` name-value pair argument value is `'off'` and 1 when the `'estdisp'` name-value pair argument value is `'on'`.
- `covb` — Estimated covariance matrix for `B`
- `se` — Vector of standard errors of the coefficient estimates `b`
- `coeffcorr` — Correlation matrix for `b`
- `t` — t statistics for `b`
- `p` — p -values for `b`
- `resid` — Vector of residuals
- `residp` — Vector of Pearson residuals
- `residd` — Vector of deviance residuals
- `resida` — Vector of Anscombe residuals

If you estimate a dispersion parameter for the binomial or Poisson distribution, then `stats.s` is set equal to `stats.sfit`. Also, the elements of `stats.se` differ by the factor `stats.s` from their theoretical values.

Examples

Fit Generalized Linear Model with Probit Link

Enter the sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
```

```
    3300 3500 3700 3900 4100 4300]';  
n = [48 42 31 34 31 21 23 23 21 16 17 21]';  
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each y value is the number of successes in the corresponding number of trials in n , and x contains the predictor variable values.

Fit a probit regression model for y on x .

```
b = glmfit(x,[y n], 'binomial', 'link', 'probit');
```

Compute the estimated number of successes and plot the percent observed and estimated percent success versus the x values.

```
yfit = glmval(b,x,'probit','size',n);  
plot(x, y./n, 'o', x, yfit./n, '-', 'LineWidth', 2)
```

Use Custom-defined Link Function

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the response and predictor variables.

```
X = meas(51:end,:);  
y = strcmp('versicolor',species(51:end));
```

Define three function handles, created using @, that define the link, the derivative of the link, and the inverse link for a logit link function, and store them in a cell array.

```
link = @(mu) log(mu ./ (1-mu));  
derlink = @(mu) 1 ./ (mu .* (1-mu));  
invlink = @(resp) 1 ./ (1 + exp(-resp));  
F = {link, derlink, invlink};
```

Fit a logistic regression using glmfit with the link function you defined.

```
b = glmfit(X,y,'binomial','link',F)
```

```
b =
```

```
42.6378  
2.4652  
6.6809  
-9.4294  
-18.2861
```

Now, fit a generalized linear model using the logit link function and compare the results.

```
b = glmfit(X,y,'binomial','link','logit')
```

```
b =
```

```
42.6378  
2.4652  
6.6809  
-9.4294  
-18.2861
```

Introduced before R2006a

glmval

Generalized linear model values

Syntax

```
yhat = glmval(b,X,link)
[yhat,dylo,dyhi] = glmval(b,X,link,stats)
[...] = glmval(...,param1,val1,param2,val2,...)
```

Description

`yhat = glmval(b,X,link)` computes predicted values for the generalized linear model with link function `link` and predictors `X`. Distinct predictor variables should appear in different columns of `X`. `b` is a vector of coefficient estimates as returned by the `glmfit` function. `link` can be any of the character vectors or custom-defined link functions used as values for the 'link' name-value pair argument in the `glmfit` function.

Note: By default, `glmval` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `glmval` using the 'constant' parameter, below.

`[yhat,dylo,dyhi] = glmval(b,X,link,stats)` also computes 95% confidence bounds for the predicted values. When the `stats` structure output of the `glmfit` function is specified, `dylo` and `dyhi` are also returned. `dylo` and `dyhi` define a lower confidence bound of `yhat-dylo`, and an upper confidence bound of `yhat+dyhi`. Confidence bounds are nonsimultaneous, and apply to the fitted curve, not to a new observation.

`[...] = glmval(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs to control the predicted values. Acceptable parameters are:

Parameter	Value
'confidence' — the confidence level for the confidence bounds	A scalar between 0 and 1

Parameter	Value
'size' — the size parameter (N) for a binomial model	A scalar, or a vector with one value for each row of X
'offset' — used as an additional predictor variable, but with a coefficient value fixed at 1.0	A vector
'constant'	<ul style="list-style-type: none"> 'on' — Includes a constant term in the model. The coefficient of the constant term is the first element of b. 'off' — Omit the constant term
'simultaneous' — Compute simultaneous confidence intervals (true), or compute non-simultaneous confidence intervals (default false)	true or false

Examples

Fit Generalized Linear Model with Probit Link

Enter the sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
      3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each **y** value is the number of successes in the corresponding number of trials in **n**, and **x** contains the predictor variable values.

Fit a probit regression model for **y** on **x**.

```
b = glmfit(x,[y n], 'binomial', 'link', 'probit');
```

Compute the estimated number of successes and plot the percent observed and estimated percent success versus the **x** values.

```
yfit = glmval(b,x,'probit','size',n);
plot(x, y./n, 'o', x,yfit./n, '-', 'LineWidth',2)
```

Use Custom-defined Link Function

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
      3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each y value is the number of successes in corresponding number of trials in n , and x contains the predictor variable values.

Now define three function handles, created using `@`, that define the link, the derivative of the link, and the inverse link for a probit link function, and store them in a cell array.

```
link = @(mu) norminv(mu);  
derlink = @(mu) 1 ./ normpdf(norminv(mu));  
invlink = @(resp) normcdf(resp);  
F = {link, derlink, invlink};
```

Fit a generalized linear model for y on x using the link function you defined.

```
b = glmfit(x,[y n], 'binomial', 'link', F);
```

Compute the estimated number of successes and plot the observed and estimated percent success versus the x values.

```
yfit = glmval(b,x,F, 'size', n);  
plot(x, y./n, 'o', x, yfit./n, '-', 'LineWidth', 2)
```

Generate Code From Function That Predicts Responses Given New Data

This example is based on “Use Custom-defined Link Function”.

Enter the sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
      3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Suppose that the inverse normal pdf is an appropriate link function for the problem.

Declare a function named `myInvNorm.m`, which accepts values of $X\beta$ and returns corresponding values of the inverse of the standard normal cdf.

```
function in = myInvNorm(mu) %#codegen
%myInvNorm Inverse of standard normal cdf for code generation
% myInvNorm is a GLM link function that accepts a numeric vector mu, and
% returns in, which is a numeric vector corresponding values of the
% inverse of the standard normal cdf.
%
in = norminv(mu);
end
```

Declare another function named `myDInvNorm.m`, which accepts values of $X\beta$ and returns corresponding values of the derivative of the link function.

```
function din = myDInvNorm(mu) %#codegen
%myDInvNorm Derivative of inverse of standard normal cdf for code
%generation
% myDInvNorm corresponds to the derivative of the GLM link function
% myInvNorm. myDInvNorm accepts a numeric vector mu, and returns din,
% which is a numeric vector corresponding values of the derivative of the
% inverse of the standard normal cdf.
%
din = 1./normpdf(norminv(mu));
end
```

Declare another function named `myInvInvNorm.m`, which accepts values of $X\beta$ and returns corresponding values of the inverse of the link function.

```
function iin = myInvInvNorm(mu) %#codegen
%myInvInvNorm Standard normal cdf for code generation
% myInvInvNorm is the inverse of the GLM link function myInvNorm.
% myInvInvNorm accepts a numeric vector mu, and returns iin, which is a
% numeric vector corresponding values of the standard normal cdf.
%
iin = normcdf(mu);
end
```

Create a structure array that specifies each of the link functions. Specifically, the structure array contains fields named 'Link', 'Derivative', and 'Inverse', and corresponding values are the names of the functions.

```
link = struct('Link','myInvNorm','Derivative','myDInvNorm',...
            'Inverse','myInvInvNorm')
```

```
link =
```

```
struct with fields:
    Link: 'myInvNorm'
    Derivative: 'myDInvNorm'
    Inverse: 'myInvInvNorm'
```

Fit a GLM for y on x using the link function `link`. Additionally, return the structure array of statistics.

```
[b,~,stats] = glmfit(x,[y n],'binomial','link',link);
```

`b` is a 2-by-1 vector of regression coefficients.

Declare a function in your current working folder called `classifyGLM.m` that:

- Accepts measurements commensurate with x , regression coefficients commensurate with b , a link function, the structure of GLM statistics, and any `glmval` name-value pair argument
- Returns predictions and confidence interval margins of error.

```
function [yhat,lo,hi] = classifyGLM(b,x,link,varargin) %#codegen
%CLASSIFYGLM Classify measurements using GLM model
% CLASSIFYGLM classifies the n observations in the n-by-1 vector x using
% using the GLM model with regression coefficients b and link function
% link, and then returns the n-by-1 vector of predicted values in yhat.
% CLASSIFYGLM also returns margins of error for the predictions using
% additional information in the GLM statistics structure stats.
narginchk(3,Inf);
if(isstruct(varargin{1}))
```

```
stats = varargin{1};  
[yhat,lo,hi] = glmval(b,x,link,stats,varargin{2:end});  
else  
yhat = glmval(b,x,link,varargin{:});  
end  
end
```

Generate a MEX function from `classifyGLM.m`. Because C uses static typing, `codegen` must determine the properties of all variables in MATLAB® files at compile time. To ensure that the MEX function can use the same inputs, using the `-args` argument, specify all of the following in this order:

- The regression coefficients `b` as a compile-time constant
- The in-sample observations `x`
- The link function as a compile-time constant
- The resulting GLM statistics as a compile-time constant
- The name `'Confidence'` as a compile-time constant
- The confidence level 0.9

To designate arguments as compile-time constants, use `coder.Constant`.

```
codegen -config:mex classifyGLM -args {coder.Constant(b),x,coder.Constant(link),coder.Constant(0.9)}
```

The MEX file `classifyGLM_mex.mexw64` generates to your present working directory. The file extension depends on your platform.

Compare predictions using `glmval` and `classifyGLM_mex`. Specify name-value pair arguments in the same order as in the `-args` argument in the call to `codegen`.

```
[yhat1,melo1,mehi1] = glmval(b,x,link,stats,'Confidence',0.9);  
[yhat2,melo2,mehi2] = classifyGLM_mex(b,x,link,stats,'Confidence',0.9);  
  
comp1 = yhat1 == yhat2;  
agree1 = sum(comp1) == numel(yhat1)  
comp2 = melo1 == melo2;  
agree2 = sum(comp2) == numel(yhat1)  
comp3 = mehi1 == mehi2;  
agree3 = sum(comp3) == numel(yhat1)  
  
agree1 =
```

```
logical
  1

agree2 =
  logical
  1

agree3 =
  logical
  1
```

The generated MEX file produces the same results as `predict`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- `glmval` generates reference C code.
- Call `glmval` within a function that you declare (that is, you cannot call `glmval` at the top level).
- This table contains additional input-and-output-argument notes and limitations.

Argument	Notes and Limitations
<code>b</code>	<code>b</code> must be a compile-time constant. That is, its value cannot change while <code>codegen</code> generates the C code. You can designate variables as compile-time constants using <code>coder.Constant</code> .
<code>X</code>	Must be a double- or single-precision numeric matrix
<code>link</code>	<ul style="list-style-type: none"> • Does not support function handles, that is, functions created using <code>@</code>. • Must be a compile-time constant.
<code>stats</code>	Must be a compile-time constant
'Constant name-value pair argument	Must be a compile-time constant
Name-value pair arguments names	Name-value pair argument names must be compile-time constants. For example, to specify a confidence level of 0.9, include <code>coder.Constant('Confidence'),0.9</code> in the <code>-args</code> value of <code>codegen</code> .

`glmfit` | `GeneralizedLinearModel` | `fitglm` | `stepwiseglm`

Introduced before R2006a

glyphplot

Glyph plot

Syntax

```
glyphplot(X)
glyphplot(X, 'glyph', 'face')
glyphplot(X, 'glyph', 'face', 'features', f)
glyphplot(X, ..., 'grid', [rows, cols])
glyphplot(X, ..., 'grid', [rows, cols], 'page', p)
glyphplot(X, ..., 'centers', C)
glyphplot(X, ..., 'centers', C, 'radius', r)
glyphplot(X, ..., 'obslabels', labels)
glyphplot(X, ..., 'standardize', method)
glyphplot(X, ..., prop1, val1, ...)
h = glyphplot(X, ...)
```

Description

`glyphplot(X)` creates a star plot from the multivariate data in the n -by- p matrix X . Rows of X correspond to observations, columns to variables. A star plot represents each observation as a “star” whose i th spoke is proportional in length to the i th coordinate of that observation. `glyphplot` standardizes X by shifting and scaling each column separately onto the interval $[0, 1]$ before making the plot, and centers the glyphs on a rectangular grid that is as close to square as possible. `glyphplot` treats NaNs in X as missing values, and does not plot the corresponding rows of X . `glyphplot(X, 'glyph', 'star')` is a synonym for `glyphplot(X)`.

`glyphplot(X, 'glyph', 'face')` creates a face plot from X . A face plot represents each observation as a “face,” whose i th facial feature is drawn with a characteristic proportional to the i th coordinate of that observation. The features are described in “Face Features” on page 29-2881.

`glyphplot(X, 'glyph', 'face', 'features', f)` creates a face plot where the i th element of the index vector f defines which facial feature will represent the i th column of

`X.f` must contain integers from 0 to 17, where 0 indicate that the corresponding column of `X` should not be plotted. See “Face Features” on page 29-2881 for more information.

`glyphplot(X, ..., 'grid', [rows, cols])` organizes the glyphs into a rows-by-cols grid.

`glyphplot(X, ..., 'grid', [rows, cols], 'page', p)` organizes the glyph into one or more pages of a rows-by-cols grid, and displays the page `p`. If `p` is a vector, `glyphplot` displays multiple pages in succession. If `p` is 'all', `glyphplot` displays all pages. If `p` is 'scroll', `glyphplot` displays a single plot with a scrollbar.

`glyphplot(X, ..., 'centers', C)` creates a plot with each glyph centered at the locations in the n -by-2 matrix `C`.

`glyphplot(X, ..., 'centers', C, 'radius', r)` creates a plot with glyphs positioned using `C`, and scale the glyphs so the largest has radius `r`.

`glyphplot(X, ..., 'obslabels', labels)` labels each glyph with the text in `labels`. By default, the glyphs are labelled 1:N. Use ' ' for blank labels.

`glyphplot(X, ..., 'standardize', method)` standardizes `X` before making the plot. Choices for *method* are

- 'column' — Maps each column of `X` separately onto the interval [0,1]. This is the default.
- 'matrix' — Maps the entire matrix `X` onto the interval [0, 1].
- 'PCA' — Transforms `X` to its principal component scores, in order of decreasing eigenvalue, and maps each one onto the interval [0, 1].
- 'off' — No standardization. Negative values in `X` may make a star plot uninterpretable.

`glyphplot(X, ..., prop1, val1, ...)` sets properties to the specified property values for all line graphics objects created by `glyphplot`.

`h = glyphplot(X, ...)` returns a matrix of handles to the graphics objects created by `glyphplot`. For a star plot, `h(:, 1)` and `h(:, 2)` contain handles to the line objects for each star's perimeter and spokes, respectively. For a face plot, `h(:, 1)` and `h(:, 2)` contain object handles to the lines making up each face and to the pupils, respectively. `h(:, 3)` contains handles to the text objects for the labels, if present.

Face Features

The following table describes the correspondence between the columns of the vector f , the value of the 'Features' input parameter, and the facial features of the glyph plot. If X has fewer than 17 columns, unused features are displayed at their default value.

Column	Facial Feature
1	Size of face
2	Forehead/jaw relative arc length
3	Shape of forehead
4	Shape of jaw
5	Width between eyes

Examples

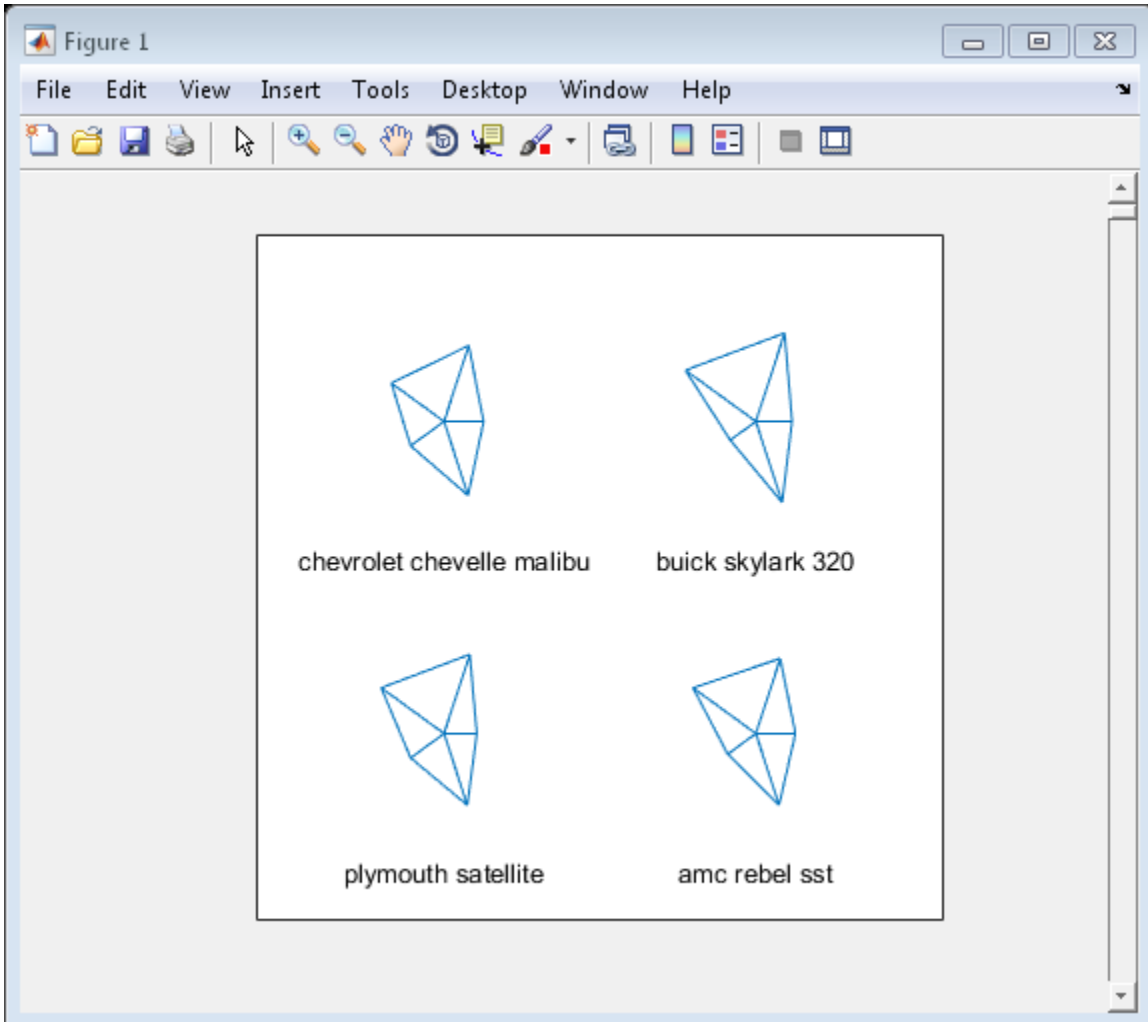

Star and Face Plots of Multivariate Data

Load the sample data.

```
load carsmall
X = [Acceleration Displacement Horsepower MPG Weight];
```

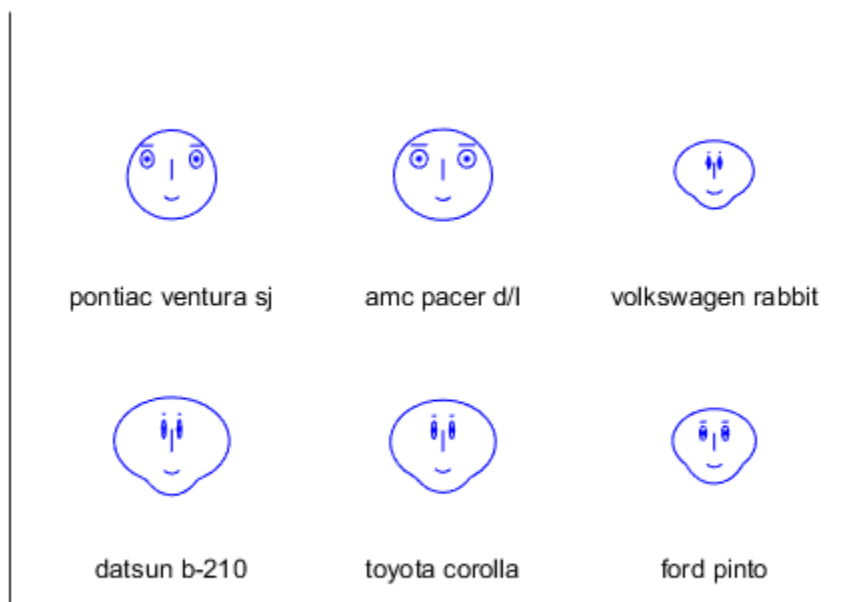

Create a star plot of the data in X . Standardize the data before plotting.

```
glyphplot(X, 'standardize', 'column', 'obslabels', Model, 'grid', [2 2], ...  
          'page', 'scroll');
```

Create a faceplot of the data in X .

```
glyphplot(X, 'glyph', 'face', 'obslabels', Model, 'grid', [2 3], 'page', 9);
```

gmdistribution class

Gaussian mixture models

Description

An object of the `gmdistribution` class defines a Gaussian mixture distribution, which is a multivariate distribution that consists of a mixture of one or more multivariate Gaussian distribution components. The number of components for a given `gmdistribution` object is fixed. Each multivariate Gaussian component is defined by its mean and covariance, and the mixture is defined by a vector of mixing proportions.

Construction

To create a Gaussian mixture distribution by specifying the distribution parameters, use the `gmdistribution` constructor. To fit a Gaussian mixture distribution model to data, use `fitgmdist`.

<code>fit</code>	Gaussian mixture parameter estimates
<code>.gmdistribution</code>	Construct Gaussian mixture distribution

Properties

All objects of the class have the properties listed in the following table.

<code>CovarianceType</code>	Type of covariance matrices
<code>DistributionName</code>	Type of distribution
<code>mu</code>	Input matrix of means μ
<code>NumComponents</code>	Number k of mixture components
<code>NumVariables</code>	Dimension d of multivariate Gaussian distributions
<code>ComponentProportion</code>	Input vector of mixing proportions
<code>ProbabilityTolerance</code>	Tolerance for posterior probabilities

SharedCovariance	<code>true</code> if all covariance matrices are restricted to be the same
Sigma	Input array of covariances

Objects constructed with `fitgmdist` have the additional properties listed in the following table.

AIC	Akaike Information Criterion
BIC	Bayes Information Criterion
Converged	Determine if algorithm converged
NumIterations	Number of iterations
NegativeLogLikelihood	Negative of log-likelihood
RegularizationValue	Value of ' <code>Regularize</code> ' parameter

Methods

<code>cdf</code>	Cumulative distribution function for Gaussian mixture distribution
<code>cluster</code>	Construct clusters from Gaussian mixture distribution
<code>disp</code>	Display Gaussian mixture distribution object
<code>display</code>	Display Gaussian mixture distribution object
<code>fit</code>	Gaussian mixture parameter estimates
<code>mahal</code>	Mahalanobis distance to component means
<code>pdf</code>	Probability density function for Gaussian mixture distribution
<code>posterior</code>	Posterior probabilities of components
<code>random</code>	Random numbers from Gaussian mixture distribution
<code>subsasgn</code>	Subscripted reference for Gaussian mixture distribution object

suboref

Subscripted reference for Gaussian mixture distribution object

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB) in the MATLAB documentation.

Examples

Fit a Gaussian Mixture Model

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function. Fit to the resulting data.

Generate the data using 1000 points from each distribution.

```
rng(1); % For reproducibility
MU1 = [1 2];
SIGMA1 = [2 0; 0 .5];
MU2 = [-3 -5];
SIGMA2 = [1 0; 0 1];
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];

scatter(X(:,1),X(:,2),10, 'r')
hold on
```

Fit a two-component Gaussian mixture model.

```
options = statset('Display','final');  
obj = fitgmdist(X,2,'Options',options);
```

```
5 iterations, log-likelihood = -7105.71
```

Plot the fit.

```
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

gmdistribution

Class: gmdistribution

Construct Gaussian mixture distribution

Syntax

```
obj = gmdistribution(mu,sigma,p)
```

Description

`obj = gmdistribution(mu,sigma,p)` constructs an object `obj` of the `gmdistribution` class defining a Gaussian mixture distribution.

`mu` is a k -by- d matrix specifying the d -dimensional mean of each of the k components.

`sigma` specifies the covariance of each component. The size of `sigma` is:

- d -by- d -by- k if there are no restrictions on the form of the covariance. In this case, `sigma(:, :, I)` is the covariance of component `I`.
- 1-by- d -by- k if the covariance matrices are restricted to be diagonal, but not restricted to be same across components. In this case, `sigma(:, :, I)` contains the diagonal elements of the covariance of component `I`.
- d -by- d matrix if the covariance matrices are restricted to be the same across components, but not restricted to be diagonal. In this case, `sigma` is the pooled estimate of covariance.
- 1-by- d if the covariance matrices are restricted to be diagonal and the same across components. In this case, `sigma` contains the diagonal elements of the pooled estimate of covariance.

`p` is an optional 1-by- k vector specifying the mixing proportions of each component. If `p` does not sum to 1, `gmdistribution` normalizes it. The default is equal proportions.

Examples

Construct a Gaussian Mixture Distribution

Create a `gmdistribution` distribution defining a two-component mixture of bivariate Gaussian distributions.

```
mu = [1 2;-3 -5];  
sigma = cat(3,[2 0;0 .5],[1 0;0 1]);  
p = ones(1,2)/2;  
obj = gmdistribution(mu,sigma,p);  
  
ezsurf(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])
```

Introduced in R2007b

gname

Add case names to plot

Syntax

```
gname(cases)
gname
h = gname(cases,line_handle)
```

Description

`gname(cases)` displays a figure window and waits for you to press a mouse button or a keyboard key. The input argument `cases` is a character array or a cell array of character vectors, in which each row of the character array or each element of the cell array contains the case name of a point. Moving the mouse over the graph displays a pair of cross-hairs. If you position the cross-hairs near a point with the mouse and click once, the graph displays the label corresponding to that point. Alternatively, you can click and drag the mouse to create a rectangle around several points. When you release the mouse button, the graph displays the labels for all points in the rectangle. Right-click a point to remove its label. When you are done labelling points, press the **Enter** or **Escape** key to stop labeling.

`gname` with no arguments labels each case with its case number.

`cases` typically contains unique case names for each point, and is a cell array of character vectors or a character matrix with each row representing a name. `cases` can also be any grouping variable, which `gname` converts to labels.

`h = gname(cases,line_handle)` returns a vector of handles to the text objects on the plot. Use the scalar `line_handle` to identify the correct line if there is more than one line object on the plot.

You can use `gname` to label plots created by the `plot`, `scatter`, `gscatter`, `plotmatrix`, and `gplotmatrix` functions.

Examples

This example uses the city ratings data sets to find out which cities are the best and worst for education and the arts.

```
load cities
education = ratings(:,6);
arts = ratings(:,7);
plot(education,arts,'+')
gname(names)
```

Click the point at the top of the graph to display its label, “New York.”

gpcdf

Generalized Pareto cumulative distribution function

Syntax

```
p = gpcdf(x,k,sigma,theta)
p = gpcdf(x,k,sigma,theta,'upper')
```

Description

`p = gpcdf(x,k,sigma,theta)` returns the cdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

`p = gpcdf(x,k,sigma,theta,'upper')` returns the complement of the cdf of the generalized Pareto (GP) distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$k < 0, 0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}.$$

gpfit

Generalized Pareto parameter estimates

Syntax

```
parmhat = gpfit(x)
[parmhat,parmci] = gpfit(x)
[parmhat,parmci] = gpfit(x,alpha)
[...] = gpfit(x,alpha,options)
```

Description

`parmhat = gpfit(x)` returns maximum likelihood estimates of the parameters for the two-parameter generalized Pareto (GP) distribution given the data in `x`. `parmhat(1)` is the tail index (shape) parameter, `k` and `parmhat(2)` is the scale parameter, `sigma`. `gpfit` does not fit a threshold (location) parameter.

`[parmhat,parmci] = gpfit(x)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gpfit(x,alpha)` returns $100(1-\alpha)\%$ confidence intervals for the parameter estimates.

`[...] = gpfit(x,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gpfit')` for parameter names and default values.

Other functions for the generalized Pareto, such as `gpcdf` allow a threshold parameter, `theta`. However, `gpfit` does not estimate `theta`. It is assumed to be known, and subtracted from `x` before calling `gpfit`.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for

$k > \theta$, or, when $k < 0$, for

$$0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}$$

gpinv

Generalized Pareto inverse cumulative distribution function

Syntax

```
x = gpinv(p,k,sigma,theta)
```

Description

`x = gpinv(p,k,sigma,theta)` returns the inverse cdf for a generalized Pareto (GP) distribution with tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter `theta`, evaluated at the values in `p`. The size of `x` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$k < 0, 0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}.$$

gplike

Generalized Pareto negative log-likelihood

Syntax

```
nlogL = gplike(params,data)
[nlogL,acov] = gplike(params,data)
```

Description

`nlogL = gplike(params,data)` returns the negative of the log-likelihood `nlogL` for the two-parameter generalized Pareto (GP) distribution, evaluated at parameters `params`. `params(1)` is the tail index (shape) parameter, `k`, and `params(2)` is the scale parameter. `gplike` does not allow a threshold (location) parameter.

`[nlogL,acov] = gplike(params,data)` returns the inverse of Fisher's information matrix, `acov`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `acov` are their asymptotic variances. `acov` is based on the observed Fisher's information, not the expected information.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$k < 0, 0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}.$$

gppdf

Generalized Pareto probability density function

Syntax

`p = gppdf(x, k, sigma, theta)`

Description

`p = gppdf(x, k, sigma, theta)` returns the pdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$k < 0, 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}.$$

gplotmatrix

Matrix of scatter plots by group

Syntax

```
gplotmatrix(x,y,group)
gplotmatrix(x,y,group,clr,sym,siz)
gplotmatrix(x,y,group,clr,sym,siz,doleg)
gplotmatrix(x,y,group,clr,sym,siz,doleg,disopt)
gplotmatrix(x,y,group,clr,sym,siz,doleg,disopt,xnam,ynam)
[h,ax,bigax] = gplotmatrix(...)
```

Description

`gplotmatrix(x,y,group)` creates a matrix of scatter plots. Each individual set of axes in the resulting figure contains a scatter plot of a column of `x` against a column of `y`. All plots are grouped by the grouping variable `group`.

`x` and `y` are matrices with the same number of rows. If `x` has p columns and `y` has q columns, the figure contains a p -by- q matrix of scatter plots. If you omit `y` or specify it as the empty matrix, `[]`, `gplotmatrix` creates a square matrix of scatter plots of columns of `x` against each other.

`group` is a grouping variable that can be a categorical variable, vector, character array, or cell array of character vectors. `group` must have the same number of rows as `x` and `y`. Points with the same value of `group` are placed in the same group, and appear on the graph with the same marker and color. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`); in that case, observations are in the same group if they have common values of all grouping variables.

`gplotmatrix(x,y,group,clr,sym,siz)` specifies the color, marker type, and size for each group. `clr` is a character array of colors recognized by the `plot` function. `sym` is a character array of symbols recognized by the `plot` command, with the default value `'.'`. `siz` is a vector of sizes, with the default value determined based on the number of observations. If you do not specify enough values for all groups, `gplotmatrix` cycles through the specified values as needed.

`gplotmatrix(x,y,group,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph (*doleg* is 'on', the default) or not (*doleg* is 'off').

`gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt)` controls what appears along the diagonal of a plot matrix of *y* versus *x*. Allowable values are 'none', to leave the diagonals blank, 'hist', to plot histograms, 'stairs' to display the outlines of grouped histograms (default if there is more than one group), 'grpbars' to plot grouped histogram bars. or 'variable', to write the variable names. `gplotmatrix` displays histograms along the diagonal only when there is only one variable (i.e., `gplotmatrix(x,[],[],[],[],[],[],[], 'hist')`).

`gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt,xnam,yname)` specifies the names of the columns in the *x* and *y* arrays. These names are used to label the *x*- and *y*-axes. *xnam* and *yname* must be character arrays or cell arrays of character vectors, with one name for each column of *x* and *y*, respectively.

`[h,ax,bigax] = gplotmatrix(...)` returns three arrays of handles. *h* is an array of handles to the lines on the graphs. The array's third dimension corresponds to groups in the input argument *group*. *ax* is a matrix of handles to the axes of the individual plots. If *dispopt* is 'hist', 'stairs', or 'grpbars', *ax* contains one extra row of handles to invisible axes in which the histograms are plotted. *bigax* is a handle to big (invisible) axes framing the entire plot matrix. *bigax* is fixed to point to the current axes, so a subsequent `title`, `xlabel`, or `ylabel` command will produce labels that are centered with respect to the entire plot matrix.

Examples

Create Grouped Data Scatter Plot Matrix

Load the sample data.

```
load discrim;
```

The `ratings` array contains rating values for 329 U.S. cities in the nine different categories listed in the `categories` array. The `group` array contains a city size code that is equal to 2 for the 26 largest cities, and 1 otherwise.

Create a matrix of scatter plots to compare the first two categories, `climate` and `housing`, with categories 4 (`crime`) and 7 (`arts`). Specify `group` as the grouping variable to visually distinguish the data for large and small cities.

```
figure;
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group);
```

The figure displays a matrix of scatter plots for the specified comparisons, with each city size group represented by a different color.

For better clarity, you can adjust the appearance of the graphs by specifying colors and plotting symbols, and labeling the axes with the rating categories.

```
figure;
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group,...
    'br','.o',[],'on',' ',categories(1:2,:),...
    categories([4 7],:));
```

gprnd

Generalized Pareto random numbers

Syntax

```
r = gprnd(k,sigma,theta)
r = gprnd(k,sigma,theta,m,n,...)
R = gprnd(K,sigma,theta,[m,n,...])
```

Description

`r = gprnd(k,sigma,theta)` returns an array of random numbers chosen from the generalized Pareto (GP) distribution with tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`. The size of `r` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `r` is the size of the other parameters.

`r = gprnd(k,sigma,theta,m,n,...)` or `R = gprnd(K,sigma,theta,[m,n,...])` generates an `m`-by-`n`-by-... array. The `k`, `sigma`, `theta` parameters can each be scalars or arrays of the same size as `r`.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$$

gpstat

Generalized Pareto mean and variance

Syntax

`[m,v] = gpstat(k,sigma,theta)`

Description

`[m,v] = gpstat(k,sigma,theta)` returns the mean of and variance for the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`.

The default value for `theta` is 0.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for `x > theta`, or when

$$k < 0, 0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}.$$

growTrees

Class: TreeBagger

Train additional trees and add to ensemble

Syntax

```
B = growTrees(B,ntrees)
```

```
B = growTrees(B,ntrees, 'param1',val1, 'param2',val2, ...)
```

Description

`B = growTrees(B,ntrees)` grows `ntrees` new trees and appends them to those trees already stored in the ensemble `B`.

`B = growTrees(B,ntrees, 'param1',val1, 'param2',val2, ...)` specifies optional parameter name/value pairs:

'NumPrint'

Specifies that a diagnostic message showing training progress should display after every `value` training cycles (grown trees). Default is no diagnostic messages.

'Options'

A `struct` that specifies options that govern computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to `statset`. You can retrieve values of the individual fields with a call to `statget`. Applicable `statset` parameters are:

- 'UseParallel' — If `true` and if a `parpool` of the Parallel Computing Toolbox is open, compute decision trees drawn on separate bootstrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a `parpool`

is not open, computation occurs in serial mode. Default is `false`, or serial computation.

- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
- `Streams` — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `growTrees` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case
 - You have an open Parallel pool
 - `UseParallel` is `true`
 - `UseSubstreams` is `false`

In that case, use a cell array the same size as the Parallel pool.

grp2idx

Create index vector from grouping variable

Syntax

```
[G,GN]=grp2idx(S)
[G,GN,GL] = grp2idx(S)
```

Description

`[G,GN]=grp2idx(S)` creates an index vector `G` from the grouping variable `S`. `S` can be a categorical, numeric, logical, datetime, or duration vector; a cell array of character vectors; or a character array with each row representing a group label. The result `G` is a vector taking integer values from 1 up to the number `K` of distinct groups. `GN` is a cell array of character vectors representing group labels. `GN(G)` reproduces `S` (aside from any differences in type).

The order of `GN` depends on the grouping variable:

- For numeric and logical grouping variables, the order is the sorted order of `S`.
- For categorical grouping variables, the order is the order of `getlabels(S)`.
- For grouping variables, the order is the order of first appearance in `S`.

`[G,GN,GL] = grp2idx(S)` returns a column vector `GL` representing the group levels. The set of groups and their order in `GL` and `GN` are the same, except that `GL` has the same type as `S`. If `S` is a character matrix, `GL(G, :)` reproduces `S`, otherwise `GL(G)` reproduces `S`.

`grp2idx` treats NaNs (numeric, duration, or logical), ' ' (empty character arrays or cell arrays of character vectors), `<undefined>` values (categorical), and NaNs (datetime) in `S` as missing values and returns NaNs in the corresponding rows of `G`. `GN` and `GL` don't include entries for missing values.

Examples

Load the data in `hospital.mat` and create a categorical grouping variable:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
AgeGroup = ordinal(hospital.Age, labels, [], edges);

ages = hospital.Age(1:5)

ages =
  38
  43
  38
  40
  49

group = AgeGroup(1:5)

group =
  30s
  40s
  30s
  40s
  40s

indices = grp2idx(group)

indices =
  4
  5
  4
  5
  5
```

Topics

“Grouping Variables” on page 2-58

Introduced before R2006a

grpstats

Summary statistics organized by group

Syntax

```
statarray = grpstats(tbl,groupvar)
statarray = grpstats(tbl,groupvar,whichstats)
statarray = grpstats(tbl,groupvar,whichstats,Name,Value)

means = grpstats(X,group)
[stats1,...,statsN] = grpstats(X,group,whichstats)
[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)

grpstats(X,group,alpha)
```

Description

`statarray = grpstats(tbl,groupvar)` returns a table or dataset array with the means for the data groups specified in `tbl` determined by the values of the grouping variable or variables specified in `groupvar`.

- If there is a single grouping variable, then there is a row in `statarray` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `groupvar` is a cell array of character vectors containing multiple grouping variable names, or a vector of column numbers, then there is a row in `statarray` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If any variables in `tbl` (other than those specified in `groupvar`) are not numeric or logical arrays, then you must specify the names or column numbers of the numeric and logical variables for which you want to calculate means using the name-value pair argument, `DataVars`.

`statarray = grpstats(tbl,groupvar,whichstats)` returns the group values for the summary statistics types specified in `whichstats`.

`statarray = grpstats(tbl,groupvar,whichstats,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`means = grpstats(X,group)` returns a column vector or matrix with the means of the groups of the data in the matrix or vector `X` determined by the values of the grouping variable or variables, `group`. The rows of `means` correspond to the grouping variable values.

- If there is a single grouping variable, then there is a row in `means` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `group` is a cell array of grouping variables, then there is a row in `means` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If `X` is a matrix, then `means` is a matrix with the same number of columns as `X`. Each column of `means` has the group means for the corresponding column of `X`.

`[stats1,...,statsN] = grpstats(X,group,whichstats)` returns column vectors or arrays with group values for the summary statistic types specified in `whichstats`.

`[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)` specifies the significance level for confidence and prediction intervals.

`grpstats(X,group,alpha)` plots the means of the groups of data in the vector or matrix `X` determined by the values of the grouping variable, `group`. The grouping variable values are on the horizontal plot axis. Each group mean has $100 \times (1 - \alpha)\%$ confidence intervals.

- If `X` is a matrix, then `grpstats` plots the means and confidence intervals for each column of `X`.
- If `group` is a cell array of grouping variables, then `grpstats` plots the means and confidence intervals for the groups of data in `X` determined by the unique combinations of values of the grouping variables. For example, if there are two grouping variables, each with two values, there are four possible combinations of grouping variable values. The plot includes only the combinations of values that exist in the input grouping variables (not all possible combinations).

Examples

Dataset Array Summary Statistics Organized by Group

Load the sample data.

```
load('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Sex`, `Age`, `Weight`, and `Smoker`.

```
dsa = hospital(:, {'Sex', 'Age', 'Weight', 'Smoker'});
```

`Sex` is a nominal array, with levels `Male` and `Female`. The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, grouped by the levels in `Sex`.

```
statarray = grpstats(dsa, 'Sex')
```

```
statarray =
```

	Sex	GroupCount	mean_Age	mean_Weight	mean_Smoker
Female	Female	53	37.717	130.47	0.24528
Male	Male	47	38.915	180.53	0.44681

`statarray` is a dataset array with two rows, corresponding to the levels in `Sex`. `GroupCount` is the number of observations in each group. The means of `Age`, `Weight`, and `Smoker`, grouped by `Sex`, are given in `mean_Age`, `mean_Weight`, and `mean_Smoker`.

Compute the mean for `Age` and `Weight`, grouped by the values in `Smoker`.

```
statarray = grpstats(dsa, 'Smoker', 'mean', 'DataVars', {'Age', 'Weight'})
```

```
statarray =
```

	Smoker	GroupCount	mean_Age	mean_Weight
0	false	66	37.97	149.91
1	true	34	38.882	161.94

In this case, not all variables in `dsa` (excluding the grouping variable, `Smoker`) are numeric or logical arrays; the variable `Sex` is a nominal array. When not all variables in the input dataset array are numeric or logical arrays, you must specify the variables for which you want to calculate summary statistics using `DataVars`.

Compute the minimum and maximum weight, grouped by the combinations of values in `Sex` and `Smoker`.

```
statarray = grpstats(dsa,{'Sex','Smoker'},{'min','max'},...
                    'DataVars','Weight')
```

```
statarray =
```

	Sex	Smoker	GroupCount	min_Weight	max_Weight
Female_0	Female	false	40	111	147
Female_1	Female	true	13	115	146
Male_0	Male	false	26	158	194
Male_1	Male	true	21	164	202

There are two unique values in `Smoker` and two levels in `Sex`, for a total of four possible combinations of values: Female Nonsmoker (`Female_0`), Female Smoker (`Female_1`), Male Nonsmoker (`Male_0`), and Male Smoker (`Male_1`).

Specify the names for the columns in the output.

```
statarray = grpstats(dsa,{'Sex','Smoker'},{'min','max'},...
                    'DataVars','Weight','VarNames',{'Gender','Smoker'},...
                    'GroupCount','LowestWeight','HighestWeight')
```

```
statarray =
```

	Gender	Smoker	GroupCount	LowestWeight	HighestWeight
Female_0	Female	false	40	111	147
Female_1	Female	true	13	115	146
Male_0	Male	false	26	158	194
Male_1	Male	true	21	164	202

Summary Statistics for a Dataset Array Without Grouping

Load the sample data.

```
load('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Age`, `Weight`, and `Smoker`.

```
dsa = hospital(:, {'Age', 'Weight', 'Smoker'});
```

The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean, minimum, and maximum for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, with no grouping.

```
statarray = grpstats(dsa, [], {'mean', 'min', 'max'})
```

```
statarray =
```

	GroupCount	mean_Age	min_Age	max_Age	mean_Weight
All	100	38.28	25	50	154
	min_Weight	max_Weight	mean_Smoker	min_Smoker	max_Smoker
All	111	202	0.34	false	true

The observation name `All` indicates that all observations in `dsa` were used to compute the summary statistics.

Group Means for a Matrix Using One or More Grouping Variables

Load the sample data.

```
load('carsmall')
```

All variables are measured for 100 cars. `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA). `Cylinders` has three unique values, 4, 6, and 8, indicating the number of cylinders in each car.

Calculate the mean acceleration, grouped by country of origin.

```
means = grpstats(Acceleration, Origin)
```

```
means =
```

```
14.4377  
18.0500  
15.8867
```

```
16.3778
16.6000
15.5000
```

`means` is a 6-by-1 vector of mean accelerations, where each value corresponds to a country of origin.

Calculate the mean acceleration, grouped by both country of origin and number of cylinders.

```
means = grpstats(Acceleration, {Origin, Cylinders})
```

```
means =
    17.0818
    16.5267
    11.6406
    18.0500
    15.9143
    15.5000
    16.3375
    16.7000
    16.6000
    15.5000
```

There are 18 possible combinations of grouping variable values because `Origin` has 6 unique values and `Cylinders` has 3 unique values. Only 10 of the possible combinations appear in the data, so `means` is a 10-by-1 vector of group means corresponding to the observed combinations of values.

Return the group names along with the mean acceleration for each group.

```
[means, grps] = grpstats(Acceleration, {Origin, Cylinders}, {'mean', 'gname'})
```

```
means =
    17.0818
    16.5267
    11.6406
    18.0500
    15.9143
```

```
15.5000
16.3375
16.7000
16.6000
15.5000
```

```
grps =
```

```
10×2 cell array
```

```
'USA'      '4'
'USA'      '6'
'USA'      '8'
'France'   '4'
'Japan'    '4'
'Japan'    '6'
'Germany'  '4'
'Germany'  '6'
'Sweden'   '4'
'Italy'    '4'
```

The output `grps` shows the 10 observed combinations of grouping variable values. For example, the mean acceleration of 4-cylinder cars made in France is 18.05.

Multiple Summary Statistics for a Matrix Organized by Group

Load the sample data.

```
load carsmall
```

The variable `Acceleration` was measured for 100 cars. The variable `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA).

Return the minimum and maximum acceleration grouped by country of origin.

```
[grpMin,grpMax,grp] = grpstats(Acceleration,Origin,{'min','max','gname'})
```

```
grpMin =
```

```
8.0000
15.3000
13.9000
12.2000
```

```

15.7000
15.5000

grpMax =

22.2000
21.9000
18.2000
24.6000
17.5000
15.5000

grp =

6×1 cell array

'USA'
'France'
'Japan'
'Germany'
'Sweden'
'Italy'

```

The sample car with the lowest acceleration is made in the USA, and the sample car with the highest acceleration is made in Germany.

Plot Prediction Intervals for a New Observation in Each Group

Load the sample data.

```
load('carsmall')
```

The variable `Weight` was measured for 100 cars. The variable `Model_Year` has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Calculate the mean weight and 90% prediction intervals for each model year.

```
[means,pred,grp] = grpstats(Weight,Model_Year,...
    {'mean','predci','gname'},'Alpha',0.1);
```

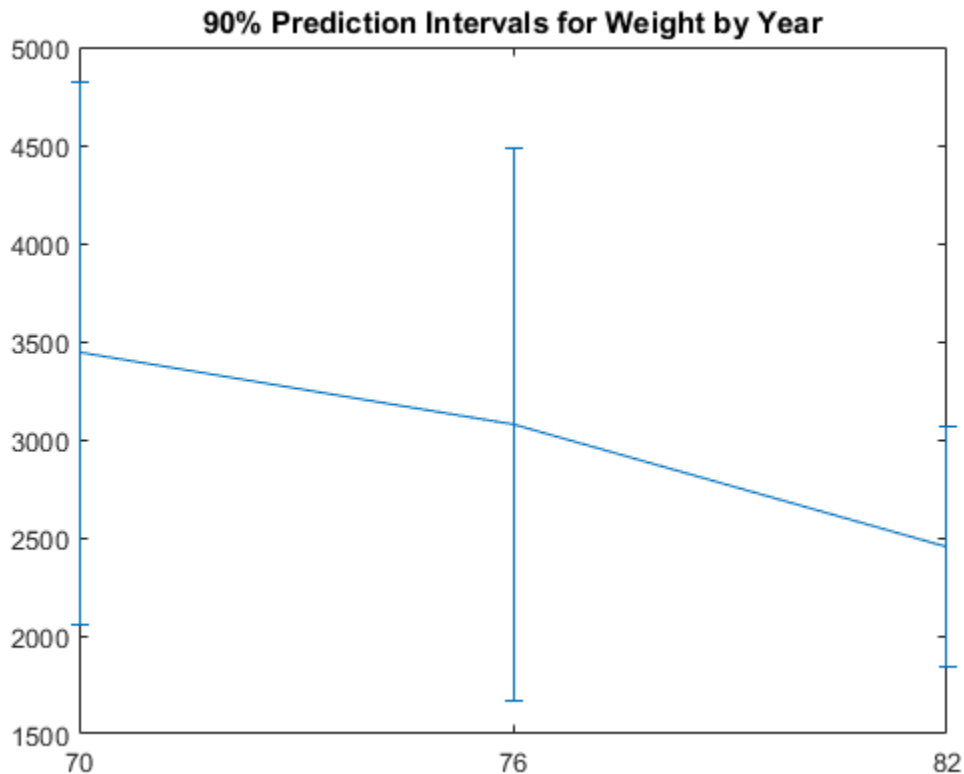

Plot error bars showing the mean weight and 90% prediction intervals, grouped by model year. Label the horizontal axis with the group names.

```

ngrps = length(grp); % Number of groups

errorbar((1:ngrps)', means, pred(:,2) - means)
set(gca, 'xtick', 1:ngrps, 'xticklabel', grp)
title('90% Prediction Intervals for Weight by Year')

```

Plot Group Means and Confidence Intervals

Load the sample data.

```
load('carsmall')
```

The variables `Acceleration` and `Weight` are the acceleration and weight values measured for 100 cars. The variable `Cylinders` is the number of cylinders in each car.

The variable `Model_Year` has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Plot mean acceleration, grouped by `Cylinders`, with 95% confidence intervals.

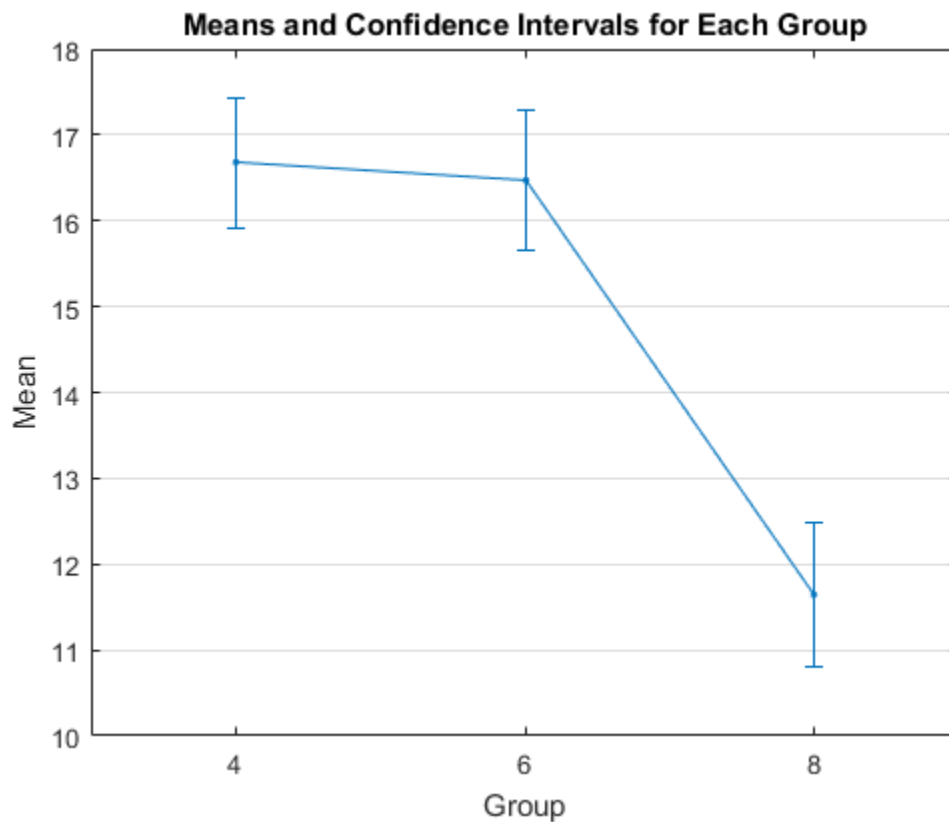

```
grpstats(Acceleration,Cylinders,0.05)
```

```
ans =
```

```
16.6706
```

```
16.4765
```

```
11.6406
```

The mean acceleration for cars with 8 cylinders is significantly lower than for cars with 4 or 6 cylinders.

Plot mean acceleration and weight, grouped by `Cylinders`, and 95% confidence intervals. Scale the `Weight` values by 1000 so the means of `Weight` and `Acceleration` are the same order of magnitude.

```
grpstats([Acceleration,Weight/1000],Cylinders,0.05)
```

```
ans =
```

```
16.6706    2.3726
16.4765    3.1255
11.6406    3.9703
```

The average weight of cars increases with the number of cylinders, and the average acceleration decreases with the number of cylinders.

Plot mean acceleration, grouped by both `Cylinders` and `Model_Year`. Specify 95% confidence intervals.

```
grpstats(Acceleration, {Cylinders, Model_Year}, 0.05)
```

ans =

```
16.1875  
16.8667  
16.7036
```

15.5000
 17.0000
 16.0333
 11.0217
 13.2222

There are nine possible combinations of grouping variable values because there are three unique values in `Cylinders` and three unique values in `Model_Year`. The plot does not show 8-cylinder cars with model year 1982 because the data did not include this combination.

The mean acceleration of 8-cylinder cars made in 1976 is significantly larger than the mean acceleration of 8-cylinder cars made in 1970.

- “Summary Statistics Grouped by Category” on page 2-43
- “Test Differences Between Category Means” on page 2-34
- “Plot Data Grouped by Category” on page 2-29
- “Calculations on Dataset Arrays” on page 2-115

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. **tbl** must include at least one variable that is a grouping variable.

Summary statistics can only be calculated for variables that have a numeric or logical data type. If any variables in **tbl** (other than the grouping variables) are not numeric or logical arrays, then use the name-value pair argument **DataVars** to specify the names or column numbers of the numeric and logical variables for which to calculate summary statistics.

groupvar — Identifiers for the grouping variables

cell array of character vectors | vector of positive integers | logical vector | []

Identifiers for the grouping variables in the input data, **tbl**, specified as one of the following:

Character vector or cell array of character vectors	Names of the grouping variables
Positive integer or vector of positive integers	Variable numbers of the grouping variables
Vector of logical values with number of elements equal to the number of variables in tbl	Logical indicator with value true for grouping variables and false otherwise
[]	No groups (returns summary statistics for all data)

Any variable that is identified by `groupvar` as a grouping variable must have a valid grouping variable data type: categorical array, logical or numeric vector, datetime or duration vector, or cell array of character vectors.

For example, consider an input table, `tbl`, with six variables. The fourth variable is named `Gender`. To be a valid grouping variable, the data type of `Gender` might be a cell array of character arrays or a nominal array, with the unique values `Male` and `Female`. To specify the variable `Gender` as the grouping variable, you can use any of these syntaxes:

- `statarray = grpstats(tbl, 'Gender')`
- `statarray = grpstats(tbl, 4)`
- `statarray = grpstats(tbl, logical([0 0 0 1 0 0]))`

Data Types: `double` | `logical` | `cell` | `char`

whichstats — Types of summary statistics

character vector | function handle

Types of summary statistics to compute, specified as a character vector or function handle, or a cell array of character vectors and function handles. Use a cell array to specify multiple types of summary statistics.

Possible values are:

<code>'mean'</code>	Mean
<code>'sem'</code>	Standard error of the mean
<code>'numel'</code>	Count, or number, of non-NaN elements
<code>'gname'</code>	Group name
<code>'std'</code>	Standard deviation
<code>'var'</code>	Variance
<code>'min'</code>	Minimum
<code>'max'</code>	Maximum
<code>'range'</code>	Range
<code>'meanci'</code>	95% confidence interval for the mean
<code>'predci'</code>	95% prediction interval for a new observation

Example: `[stat1,stat2] = grpstats(X,group,{'mean','sem'})`

You can specify different significance levels for the 'meanci' and 'predci' options using the name-value pair argument, `Alpha`.

To specify other types of summary statistics, you can use function handles. You can use the handle to any function that accepts a column or matrix of data, and returns the same size output each time `grpstats` calls it (even if the output for some groups is empty).

If the function accepts a column of data, then the function can return either a scalar value, or an *nvals*-by-1 column vector for descriptive statistics of length *nvals* (for example, confidence intervals have length two). If the function accepts a matrix, it must either return a 1-by-*ncols* row vector, or an *nvals*-by-*ncols* matrix, where *ncols* is the number of columns in the input data matrix.

```
Example: [stat1,stat2,stat3] = grpstats(X,group,
{'mean','std',@skewness})
```

For functions that do not compute column-wise statistics, specify the computation direction while specifying the function.

```
Example: stat1 = grpstats(X,group,@(x)sum(x,1))
```

Data Types: char | function_handle

alpha — Significance level

scalar value in the range (0,1)

Significance level, specified as a scalar value in the range (0,1).

- When you specify 'meanci' or 'predci' in `whichstats`, you can use `alpha` to specify the significance level for the confidence or prediction intervals. If you specify `alpha`, then `grpstats` returns $100 \times (1 - \text{alpha})\%$ confidence or prediction intervals. If you do not specify `alpha`, then `grpstats` returns 95% intervals (`alpha = 0.05`).
- Use `alpha` with the `grpstats(X,group,alpha)` syntax to plot group means and corresponding $100 \times (1 - \text{alpha})\%$ confidence intervals.

Data Types: double

X — Input data

vector | matrix

Input data, specified as a vector or a matrix. If `X` is a matrix, then `grpstats` returns summary statistics for each column of `X`.

Data Types: double | single

group — Grouping variable

categorical array | logical or numeric vector | datetime or duration vector | cell array of character vectors | []

Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of character vectors. Each unique value in a grouping variable defines a group. `grpstats` groups data for summary statistics using the grouping variable values.

There must be a grouping variable value for each row of the input data `X`. Observations (rows) with the same value of the grouping variable are in the same group. Use [] to compute summary statistics for all data, without using groups.

For example, if `Gender` is a cell array of character vectors with values 'Male' and 'Female', you can use `Gender` as a grouping variable to summarize your data by gender.

You can also use more than one grouping variable to group data for summary statistics. In this case, specify a cell array of grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array {`Gender`, `Smoker`} divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker. `grpstats` returns summary statistics only for the combinations of values that exist in the input grouping variables (not all possible combinations).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'DataVars', [1,3,4], 'Alpha', 0.01` specifies that summary statistics be calculated for the 1st, 3rd, and 4th variables in a dataset array, with 99% confidence intervals.

'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level for confidence and prediction intervals, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

When you include `'meanci'` or `'predci'` in `whichstats`, you can use `Alpha` to specify the significance level for confidence or prediction intervals. If you specify the value a , then `grpstats` returns $100 \times (1 - a)\%$ confidence or prediction intervals.

If you do not specify a value for `Alpha`, then `grpstats` returns 95% intervals ($a = 0.05$).

Example: `'Alpha', 0.1`

Data Types: `double`

'DataVars' — Variable names or columns

cell array of character vectors | vector of positive integers | logical vector

Variable names or columns indicating which variables in the input data `tbl` you want to compute summary statistics for, specified as the comma-separated pair consisting of `'DataVars'` and a cell array of character vectors, vector of positive integers, or a logical vector. Use a character vector to specify a variable name, a positive integer to specify a variable column number, or logical values to indicate which variables to include (`true` if you want to compute summary statistics, `false` otherwise).

You must specify `DataVars` if there are any variables in `tbl` (other than the grouping variables specified in `groupvar`) that are not numeric or logical arrays. Summary statistics can only be calculated for variables that have a numeric or logical data type.

Example: `'DataVars', {'Height', 'Weight'}`

Data Types: `double` | `cell` | `char`

'VarNames' — Variable names for output

cell array of character vectors

Variable names for the output `statarray`, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of character vectors. By default, `grpstats` constructs output variable names by appending a prefix to the variable names from the input data `tbl`. This prefix corresponds to the summary statistic name.

Example: `'VarNames', {'Gender', 'GroupCount', 'MaleMean', 'FemaleMean'}`

Data Types: `cell`

Output Arguments

statarray — Group summary statistics

table | dataset array

Group summary statistics, returned as a table or a dataset array. If `tbl` is a table, `grpstats` returns `statarray` as a table. If `tbl` is a dataset array, `grpstats` returns `statarray` as a dataset array.

`statarray` contains summary statistic values for the groups of data in `tbl` determined by the levels of the grouping variables specified by `groupvar`. There is a row in `statarray` for each observed value or combination of values in the variables specified by `groupvar`. The output `statarray` contains:

- All grouping variables specified by `groupvar`.
- The variable `GroupCount`, containing the number of observations in each group.
- Group summary statistic values for all variables in `tbl` (other than those specified by `groupvar`), or for only the variables specified using `DataVars`.

The total number of variables in `statarray` is $ngroupvars + 1 + ndatavars \times nstats$, where $ngroupvars$ is the number of variables in `groupvar`, $ndatavars$ is the number of variables for which summary statistics are computed, and $nstats$ is the number of summary statistic types specified in `whichstats`.

`grpstats` assigns default names to the variables in `statarray`, unless you specify variable names using the name-value pair argument `VarNames`.

means — Group means

column vector | array

Group means for the groups of data in the vector or matrix `X` determined by the levels of `group`, returned as an *ngroups-by-ncols* array. Here, *ngroups* is the number of unique values in the grouping variable, and *ncols* is the number of columns in `X`. If `X` is a vector, then `means` is a column vector.

stats1, ..., statsN — Group summary statistics

column vectors | arrays

Group summary statistics for the groups of data in the vector or matrix `X` determined by the levels of `group`, returned as *ngroups-by-ncols* arrays. Here, *ngroups* is the number of unique values in the grouping variable, and *ncols* is the number of columns in `X`. You must specify an output argument for each type of summary statistic specified in `whichstats`.

If a summary statistic type in `whichstats` returns a value of length *nvals* (for example, a confidence interval is a descriptive statistic of length two), then the corresponding output argument is an *ngroups-by-ncols-by-nvals* array.

Algorithms

- `grpstats` treats NaNs as missing values, and removes them from the input data before calculating summary statistics.
- `grpstats` ignores empty group names.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Tall Arrays

This function supports tall arrays for out-of-memory data with some limitations.

- If the input data is a tall array, then all grouping variables must also be tall and have the same number of rows as the data.
- The `whichstats` option cannot be specified as a function handle. In addition to the current built-in options, `whichstats` can also be:
 - `'Count'` — Number of non-NaN.
 - `'NNZ'` — Number of nonzeros and non-NaN.
 - `'Kurtosis'` — Compute kurtosis.
 - `'Skewness'` — Compute skewness.
 - `'all-stats'` — Compute all summary statistics.
- Group order is not guaranteed to be the same as the in-memory `grpstats` computation.
- Summary statistics for *nonnumeric* variables return NaNs.
- `grpstats` always operates on the first dimension.
- If the input is a tall table, then the output is also a tall table. However, rather than including row names, the output tall table contains an extra variable `GroupLabel` that contains the same information.

For more information, see “Tall Arrays” (MATLAB).

grpstats

Class: RepeatedMeasuresModel

Compute descriptive statistics of repeated measures data by group

Syntax

```
statstbl = grpstats(rm,g)
statstbl = grpstats(rm,g,stats)
```

Description

`statstbl = grpstats(rm,g)` returns the count, mean, and variance for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

`statstbl = grpstats(rm,g,stats)` returns the statistics specified by `stats` for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

g — Name of grouping factor or factors

character vector | cell array of character vectors

Name of grouping factor or factors, specified as a character vector or cell array of character vectors.

Example: 'Drug'

Example: {'Drug', 'Sex'}

Data Types: char

stats — Statistics to compute

character vector | function handle | cell array of multiple character vectors and function handles

Statistics to compute, specified as one of the following:

- Character vector specifying the name of the statistics to compute. Names can be one of the following.

Name	Description
'mean'	Mean
'sem'	Standard error of the mean
'numel'	Count or number of elements
'gname'	Group name
'std'	Standard deviation
'var'	Variance
'min'	Minimum
'max'	Maximum
'range'	Maximum minus minimum
'meanci'	95% confidence interval for the mean
'predci'	95% prediction interval for a new observation

- Function handle — The function you specify must accept a vector of response values for a single group, and compute descriptive statistics for it. A function should typically return a value that has one row. A function must return the same size output each time `grpstats` calls it, even if the input for some groups is empty.
- A cell array of character vectors and function handles.

Example: @median

Example: @skewness

Example: 'gname'

Example: {'gname', 'range', 'predci'}

Data Types: char | function_handle | cell

Output Arguments

statstbl1 — Statistics values for each group

table

Statistics values for each group, returned as a table.

Examples

Compute Group Statistics

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Compute group counts, mean, and standard deviation with respect to species.

```
grpstats(rm,'species')
```

```
ans =
```

```
3×4 table
```

species	GroupCount	mean	std
_____	_____	_____	_____

```
'setosa'      200      2.5355    1.8483
'versicolor' 200      3.573    1.7624
'virginica'   200      4.285    1.9154
```

Now, compute the range of data and 95% confidence intervals for the group means for the factor species. Also display the group name.

```
grpstats(rm, 'species', {'gname', 'range', 'predci'})
```

```
ans =
```

```
3×5 table
```

species	gname	GroupCount	range	predci	
'setosa'	'setosa'	200	5.7	-1.1185	6.1895
'versicolor'	'versicolor'	200	6	0.088976	7.057
'virginica'	'virginica'	200	6.5	0.4985	8.0715

Statistics for Data Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Compute group counts, mean, standard deviation, skewness, and kurtosis of data grouped by the factors `Group` and `Gender`.

```
GS = grpstats(rm, {'Group', 'Gender'}, {'mean', 'std', @skewness, @kurtosis})
```

GS =

6×7 table

Group	Gender	GroupCount	mean	std	skewness	kurtosis
A	Female	40	16.554	21.498	0.35324	3.7807
A	Male	40	9.8335	20.602	-0.38722	2.7834
B	Female	40	11.261	25.779	-0.49177	4.1484
B	Male	40	3.6078	24.646	0.55447	2.7966
C	Female	40	-11.335	27.186	1.7499	6.1429
C	Male	40	-14.028	31.984	1.7362	5.141

Tips

- `grpstats` computes results separately for each group. The results do not depend on the fitted repeated measures model. It computes the results on all available data, without omitting entire rows that contain NaNs.

`fitrm` | `plot`

gscatter

Scatter plot by group

Syntax

```
gscatter(x,y,group)
gscatter(x,y,group,clr,sym,siz)
gscatter(x,y,group,clr,sym,siz,doleg)
gscatter(x,y,group,clr,sym,siz,doleg,xnam,ynam)
h = gscatter(...)
```

Description

`gscatter(x,y,group)` creates a scatter plot of `x` and `y`, grouped by `group`. `x` and `y` are vectors of the same size. `group` is a grouping variable in the form of a categorical variable, vector, character array, or cell array of character vectors. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`), in which case observations are in the same group if they have common values of all grouping variables. Points in the same group appear on the graph with the same marker and color.

`gscatter(x,y,group,clr,sym,siz)` specifies the color, marker type, and size for each group. `clr` is either a character array of colors recognized by the `plot` function or a three-column matrix of color specifications. `sym` is a character array of symbols recognized by the `plot` command, with the default value `'.'`. `siz` is a vector of sizes, with the default value determined based on the number of observations. If you do not specify enough values for all groups, `gscatter` cycles through the specified values as needed.

`gscatter(x,y,group,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph (`doleg` is `'on'`, the default) or not (`doleg` is `'off'`).

`gscatter(x,y,group,clr,sym,siz,doleg,xnam,ynam)` specifies the name to use for the `x`-axis and `y`-axis labels. If the `x` and `y` inputs are simple variable names and `xnam` and `ynam` are omitted, `gscatter` labels the axes with the variable names.

`h = gscatter(...)` returns an array of handles to the lines on the graph.

Examples

Scatter Plot of Climate and Housing Ratings

Load the sample data.

```
load discrim
```

The sample data contains ratings of cities according to nine factors such as climate, housing, education, and health in the matrix `ratings`.

Plot the relationship between the ratings for climate (first column) and housing (second column) grouped by city size in the matrix `group`. Choose different colors and plotting symbols for each group.

```
figure;  
gscatter(ratings(:,1),ratings(:,2),group,'br','xo')  
xlabel('climate');  
ylabel('housing');
```

Introduced before R2006a

gt

Class: grandstream

Greater than relation for handles

Syntax

`h1 > h2`

Description

`h1 > h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = gt(h1, h2)` stores the result in a logical array of the same dimensions.

prob.HalfNormalDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Half-normal probability distribution object

Description

`prob.HalfNormalDistribution` is an object consisting of parameters, a model description, and sample data for a half-normal probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitter app.

Construction

`pd = makedist('HalfNormal')` creates a half-normal probability distribution object using the default parameter values `mu = 0` and `sigma = 1`.

`pd = makedist('HalfNormal', 'mu', mu, 'sigma', sigma)` creates a half-normal distribution object using the parameter values specified for `mu` and `sigma`.

Input Arguments

mu — Location parameter

0 (default) | scalar value

Location parameter of the half-normal distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

1 (default) | positive scalar value

Scale parameter of the half-normal distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Properties

mu — Location parameter

scalar value

Location parameter of the half-normal distribution, stored as a scalar value. The `mu` parameter is also the lower limit of the half-normal distribution.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the half-normal distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

character vector

Probability distribution name, stored as a character vector. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

Distribution parameter descriptions, stored as a cell array of character vectors. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of character vectors

Distribution parameter names, stored as a cell array of character vectors. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative log likelihood of probability distribution object

<code>paramci</code>	Confidence intervals for probability distribution parameters
<code>proflik</code>	Profile likelihood function for probability distribution object
<code>std</code>	Standard deviation of probability distribution object
<code>var</code>	Variance of probability distribution object

Examples

Create a Half-Normal Distribution Object Using Default Parameters

```
pd = makedist('HalfNormal')
```

```
pd =  
  
HalfNormalDistribution  
  
Half Normal distribution  
  mu = 0  
  sigma = 1
```

Create a Half-Normal Distribution Object Using Specified Parameters

Create a half-normal distribution object. Specify `mu` equal to 0 and `sigma` equal to 1.5.

```
pd = makedist('HalfNormal','mu',0,'sigma',1.5)
```

```
pd =  
  
HalfNormalDistribution  
  
Half Normal distribution  
  mu = 0  
  sigma = 1.5
```

Compute the mean and standard deviation of the distribution.

```
m = mean(pd)
s = std(pd)
```

```
m =
    1.1968
```

```
s =
    0.9042
```

Fit a Half-Normal Distribution Object

Generate 100 random numbers from a standard normal distribution and compute their absolute value.

```
rng default % For reproducibility
x = abs(random(makedist('Normal'),100,1));
```

Fit a half-normal distribution object to the sample data.

```
pd = fitdist(x,'HalfNormal')
```

```
pd =
    HalfNormalDistribution

    Half Normal distribution
        mu =          0
        sigma = 1.1631 [1.02184, 1.35006]
```

Calculate the mean of the fitted half-normal distribution using the probability distribution object.

```
m = mean(pd)
```

```
m =
    0.9280
```

Calculate the mean of the half-normal distribution by substituting the fitted `mu` and `sigma` parameter values into the formula

$$mean = \mu + \sigma \sqrt{\frac{2}{\pi}}.$$

```
mcalc = pd.mu + pd.sigma*(sqrt(2/pi))
```

```
mcalc =
```

```
0.9280
```

Definitions

Half-Normal Distribution

The half-normal distribution is a special case of the folded normal and truncated normal distributions. Applications of the half-normal distribution include modeling measurement data and lifetime data.

The half-normal distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Location parameter	$-\infty < \mu < \infty$
<code>sigma</code>	Scale parameter	$\sigma \geq 0$

For more information, see “Half-Normal Distribution” on page B-72.

Class Attributes (MATLAB)

Property Attributes (MATLAB)

Introduced in R2016a

haltonset class

Superclasses: grandset

Halton quasi-random point sets

Description

haltonset is a quasi-random point set class that produces points from the Halton sequence.

Construction

.haltonset	Construct Halton quasi-random point set
------------	---

Methods

Inherited Methods

Methods in the following table are inherited from grandset.

disp	Display grandset object
end	Last index in indexing expression for point set
length	Length of point set
ndims	Number of dimensions in matrix
net	Generate quasi-random point set
scramble	Scramble quasi-random point set
size	Number of dimensions in matrix
suboref	Subscripted reference for grandset

Properties

Inherited Properties

Properties in the following table are inherited from `grandset`.

Dimensions	Number of dimensions
Leap	Interval between points
ScrambleMethod	Settings that control scrambling
Skip	Number of initial points to omit from sequence
Type	Name of sequence on which point set P is based

Copy Semantics

Handle. To learn how this affects your use of the class, see [Comparing Handle and Value Classes \(MATLAB\)](#) in the MATLAB Object-Oriented Programming documentation.

`sobolset`

Topics

"Quasi-Random Point Sets" on page 7-19

haltonset

Class: haltonset

Construct Halton quasi-random point set

Syntax

```
p = haltonset(d)
p = haltonset(d,prop1,val1,prop2,val2,...)
```

Description

`p = haltonset(d)` constructs a d -dimensional point set `p` of the `haltonset` class, with default property settings.

`p = haltonset(d,prop1,val1,prop2,val2,...)` specifies property name/value pairs used to construct `p`.

The object `p` returned by `haltonset` encapsulates properties of a specified quasi-random sequence. The point set is finite, with a length determined by the `Skip` and `Leap` properties and by limits on the size of point set indices (maximum value of 2^{53}). Values of the point set are not generated and stored in memory until you access `p` using `net` or parenthesis indexing.

Examples

Generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
        ScrambleMethod : none
```

Use `scramble` to apply reverse-radix scrambling:

```
p = scramble(p, 'RR2')
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
        ScrambleMethod : RR2
```

Use `net` to generate the first four points:

```
X0 = net(p,4)
X0 =
    0.0928    0.6950    0.0029
    0.6958    0.2958    0.8269
    0.3013    0.6497    0.4141
    0.9087    0.7883    0.2166
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11,:)
X =
    0.0928    0.6950    0.0029
    0.9087    0.7883    0.2166
    0.3843    0.9840    0.9878
    0.6831    0.7357    0.7923
```

`net` | `scramble` | `sobolset`

Introduced in R2008a

harmmean

Harmonic mean

Syntax

```
m = harmmean(X)
harmmean(X,dim)
```

Description

`m = harmmean(X)` calculates the harmonic mean of a sample. For vectors, `harmmean(x)` is the harmonic mean of the elements in `x`. For matrices, `harmmean(X)` is a row vector containing the harmonic means of each column. For N -dimensional arrays, `harmmean` operates along the first nonsingleton dimension of `X`.

`harmmean(X,dim)` takes the harmonic mean along dimension `dim` of `X`.

The harmonic mean is

$$m = \frac{n}{\sum_{i=1}^n \frac{1}{x_i}}$$

Examples

The arithmetic mean is greater than or equal to the harmonic mean.

```
x = exprnd(1,10,6);
```

```
harmonic = harmmean(x)
```

```
harmonic =
```

```
0.3382 0.3200 0.3710 0.0540 0.4936 0.0907
```

```
average = mean(x)
```

```
average =
```

1.3509 1.1583 0.9741 0.5319 1.0088 0.8122

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Tall Arrays

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

mean | median | geomean | trimmean

Introduced before R2006a

hist3

Bivariate histogram

Syntax

```
hist3(X)
hist3(X,nbins)
hist3(X,ctrs)
hist3(X,'Edges',edges)
N = hist3(X,...)
[N,C] = hist3(X,...)
hist3(...,param1,val1,param2,val2,...)
```

Description

`hist3(X)` bins the elements of the m -by-2 matrix `X` into a 10-by-10 grid of equally spaced containers, and plots a histogram. Each column of `X` corresponds to one dimension in the bin grid.

`hist3(X,nbins)` plots a histogram using an `nbins(1)`-by-`nbins(2)` grid of bins. `hist3(X,'Nbins',nbins)` is equivalent to `hist3(X,nbins)`.

`hist3(X,ctrs)`, where `ctrs` is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2-D grid of bins centered on `ctrs{1}` in the first dimension and on `ctrs{2}` in the second. `hist3` assigns rows of `X` falling outside the range of that grid to the bins along the outer edges of the grid, and ignores rows of `X` containing NaNs. `hist3(X,'Ctrs',ctrs)` is equivalent to `hist3(X,ctrs)`.

`hist3(X,'Edges',edges)`, where `edges` is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2-D grid of bins with edges at `edges{1}` in the first dimension and at `edges{2}` in the second. The (i,j) th bin includes the value `X(k,:)` if

```
edges{1}(i) <= X(k,1) < edges{1}(i+1)
edges{2}(j) <= X(k,2) < edges{2}(j+1)
```

Rows of X that fall on the upper edges of the grid, `edges{1}(end)` or `edges{2}(end)`, are counted in the (I, j) th or (i, J) th bins, where I and J are the lengths of `edges{1}` and `edges{2}`. `hist3` does not count rows of X falling outside the range of the grid. Use `-Inf` and `Inf` in `edges` to include all non-NaN values.

`N = hist3(X, ...)` returns a matrix containing the number of elements of X that fall in each bin of the grid, and does not plot the histogram.

`[N,C] = hist3(X, ...)` returns the positions of the bin centers in a 1-by-2 cell array of numeric vectors, and does not plot the histogram. `hist3(ax,X, ...)` plots onto an `axes` with handle `ax` instead of the current `axes`. See the `axes` reference page for more information about handles to plots.

`hist3(...,param1,val1,param2,val2,...)` allows you to specify graphics parameter name/value pairs to fine-tune the plot.

Examples

Plot Density Histogram with Intensity Map

Load the sample data.

```
load seamount
```

Correct grid for negative y-values and draw histogram in 2D.

```
hold on  
dat = [-y,x];  
hist3(dat)
```

Extract histogram data.

```
n = hist3(dat); % default is to 10x10 bins
n1 = n';
n1(size(n,1) + 1, size(n,2) + 1) = 0;
```

Generate grid for 2-D projected view of intensities.

```
xb = linspace(min(dat(:,1)),max(dat(:,1)),size(n,1)+1);
yb = linspace(min(dat(:,2)),max(dat(:,2)),size(n,1)+1);
```

Make a pseudocolor plot.

```
h = pcolor(xb,yb,n1);
```

Set the z-level and colormap of the displayed grid, and display the default 3-D perspective view.

```
h.ZData = ones(size(n1)) * -max(max(n));
colormap(hot) % heat map
title('Seamount:Data Point Density Histogram and Intensity Map');
grid on
view(3);
```

Histogram with Semi-Transparent Bars

Load the sample data.

```
load carbig
```

Use the data to make histogram on a 7-by-7 grid of bins.

```
X = [MPG,Weight];
hist3(X,[7 7]);
xlabel('MPG'); ylabel('Weight');
```

Make a histogram with semi-transparent bars.

```
hist3(X,[7 7], 'FaceAlpha', .65);  
xlabel('MPG'); ylabel('Weight');  
set(gcf, 'renderer', 'opengl');
```

Specify bin centers, different in each direction; get back counts, but don't make the plot.

```
cnt = hist3(X, {0:10:50 2000:500:5000});
```

Histogram Bars Colored According to Height

Load the sample data.

```
load carbig
```

Make a histogram on a 7-by-7 grid of bins.

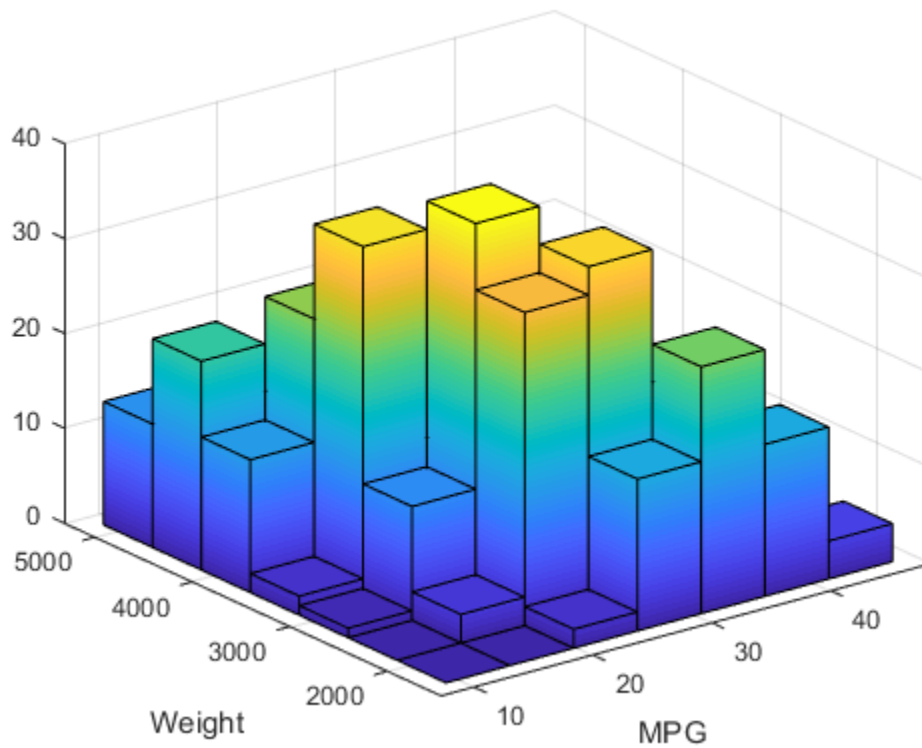

```
X = [MPG,Weight];
hist3(X,[7 7]);
```

```
xlabel('MPG'); ylabel('Weight');  
set(gcf, 'renderer', 'opengl');
```

Color the bars based on the frequency of the observations, i.e. according to the height of the bars.

```
set(get(gca, 'child'), 'FaceColor', 'interp', 'CDataMode', 'auto');
```

histfit

Histogram with a distribution fit

Syntax

```
histfit(data)  
histfit(data,nbins)  
histfit(data,nbins,dist)
```

```
h = histfit(____)
```

Description

`histfit(data)` plots a histogram of values in `data` using the number of bins equal to the square root of the number of elements in `data` and fits a normal density function.

`histfit(data,nbins)` plots a histogram using `nbins` bins and fits a normal density function.

`histfit(data,nbins,dist)` plots a histogram with `nbins` bins and fits a density function from the distribution specified by `dist`.

`h = histfit(____)` returns a vector of handles `h`, where `h(1)` is the handle to the histogram and `h(2)` is the handle to the density curve. It can include any of the input arguments in previous syntaxes.

Examples

Histogram with a Normal Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default; % For reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```
histfit(r)
```

Histogram for a Given Number of Bins

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default; % For reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram using six bins with a normal distribution fit.

```
histfit(r,6)
```

Histogram with a Specified Distribution Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng default; % For reproducibility  
b = betarnd(3,10,100,1);
```

Construct a histogram using 10 bins with a beta distribution fit.

```
histfit(b,10,'beta')
```

Histogram with a Kernel Smoothing Function Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng default; % For reproducibility  
b = betarnd(3,10,[100,1]);
```

Construct a histogram using 10 bins with a smoothing function fit.

```
histfit(b,10,'kernel')
```

Handle for a Histogram with a Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default % for reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```
h = histfit(r,10,'normal')
```

```
h =
```

2×1 graphics array:

Bar
Line

Change the bar colors of the histogram.

```
h(1).FaceColor = [.8 .8 1];
```

Change the color of the density curve.

```
h(2).Color = [.2 .2 .2];
```

Input Arguments

data — Input data

vector

Input data, specified as a vector.

Example: `data = [1.5 2.5 4.6 1.2 3.4]`

Example: `data = [1.5 2.5 4.6 1.2 3.4]'`

Data Types: `double` | `single`

nbins — Number of bins

positive integer | []

Number of bins for the histogram, specified as a positive integer. Default value is the square root of the number of elements in `data`, rounded up. Use [] for the default number of bins when fitting a distribution.

Example: `y = histfit(x,8)`

Example: `y = histfit(x,10,'gamma')`

Example: `y = histfit(x,[],'weibull')`

Data Types: double | single

dist — Distribution to fit

'normal' (default) | character vector

Distribution to fit to the histogram, specified as a character vector. The following table shows the supported distributions.

dist	Description
'beta'	Beta
'birnbaumsaunders'	Birnbaum-Saunders
'burr'	Burr Type XII
'exponential'	Exponential
'extreme value' or 'ev'	Extreme value
'gamma'	Gamma
'generalized extreme value' or 'gev'	Generalized extreme value
'generalized pareto' or 'gp'	Generalized Pareto (threshold 0)
'inversegaussian'	Inverse Gaussian
'logistic'	Logistic
'loglogistic'	Loglogistic
'lognormal'	Lognormal
'nakagami'	Nakagami
'negative binomial' or 'nbin'	Negative binomial

dist	Description
'normal'	Normal
'poisson'	Poisson
'rayleigh'	Rayleigh
'rician'	Rician
'tlocation-scale'	t location-scale
'weibull' or 'wbl'	Weibull
'kernel'	Nonparametric kernel-smoothing distribution. The density is evaluated at 100 equally spaced points that cover the range of the data in <code>data</code> . It works best with continuously distributed samples.

Data Types: char

Output Arguments

h — Handles for the plot

plot handle

Handles for the plot, returned as a vector, where `h(1)` is the handle to the histogram, and `h(2)` is the handle to the density curve.

Introduced before R2006a

hmmdecode

Hidden Markov model posterior state probabilities

Syntax

```
PSTATES = hmmdecode(seq, TRANS, EMIS)
[PSTATES, logpseq] = hmmdecode(...)
[PSTATES, logpseq, FORWARD, BACKWARD, S] = hmmdecode(...)
hmmdecode(..., 'Symbols', SYMBOLS)
```

Description

`PSTATES = hmmdecode(seq, TRANS, EMIS)` calculates the posterior state probabilities, `PSTATES`, of the sequence `seq`, from a hidden Markov model. The posterior state probabilities are the conditional probabilities of being at state k at step i , given the observed sequence of symbols, `sym`. You specify the model by a transition probability matrix, `TRANS`, and an emissions probability matrix, `EMIS`. `TRANS(i, j)` is the probability of transition from state i to state j . `EMIS(k, seq)` is the probability that symbol `seq` is emitted from state k .

`PSTATES` is an array with the same length as `seq` and one row for each state in the model. The (i, j) th element of `PSTATES` gives the probability that the model is in state i at the j th step, given the sequence `seq`.

Note The function `hmmdecode` begins with the model in state 1 at step 0, prior to the first emission. `hmmdecode` computes the probabilities in `PSTATES` based on the fact that the model begins in state 1.

`[PSTATES, logpseq] = hmmdecode(...)` returns `logpseq`, the logarithm of the probability of sequence `seq`, given transition matrix `TRANS` and emission matrix `EMIS`.

`[PSTATES, logpseq, FORWARD, BACKWARD, S] = hmmdecode(...)` returns the forward and backward probabilities of the sequence scaled by `S`.

`hmmdecode(..., 'Symbols', SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

Examples

```
trans = [0.95,0.05;  
         0.10,0.90];  
emis = [1/6 1/6 1/6 1/6 1/6 1/6;  
        1/10 1/10 1/10 1/10 1/10 1/2];  
  
[seq,states] = hmmgenerate(100,trans,emis);  
pStates = hmmdecode(seq,trans,emis);  
[seq,states] = hmmgenerate(100,trans,emis,...  
    'Symbols',{'one','two','three','four','five','six'})  
pStates = hmmdecode(seq,trans,emis,...  
    'Symbols',{'one','two','three','four','five','six'});
```

`hmmgenerate` | `hmmestimate` | `hmmviterbi` | `hmmtrain`

Introduced before R2006a

hmmestimate

Hidden Markov model parameter estimates from emissions and states

Syntax

```
[TRANS,EMIS] = hmmestimate(seq,states)
hmmestimate(...,'Symbols',SYMBOLS)
hmmestimate(...,'Statenames',STATENAMES)
hmmestimate(...,'Pseudoemissions',PSEUDOE)
hmmestimate(...,'Pseudotransitions',PSEUDOTR)
```

Description

`[TRANS,EMIS] = hmmestimate(seq,states)` calculates the maximum likelihood estimate of the transition, `TRANS`, and emission, `EMIS`, probabilities of a hidden Markov model for sequence, `seq`, with known states, `states`.

`hmmestimate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmestimate(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array or a cell array of the names of the states. The default state names are 1 through `M`, where `M` is the number of states.

`hmmestimate(...,'Pseudoemissions',PSEUDOE)` specifies pseudocount emission values in the matrix `PSEUDOE`. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. `PSEUDOE` should be a matrix of size m -by- n , where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the $i \rightarrow k$ emission does not occur in `seq`, you can set `PSEUDOE(i,k)` to be a positive number representing an estimate of the expected number of such emissions in the sequence `seq`.

`hmmestimate(...,'Pseudotransitions',PSEUDOTR)` specifies pseudocount transition values. You can use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. `PSEUDOTR` should be a matrix of size m -by- m , where m is the number of states

in the hidden Markov model. If the $i \rightarrow j$ transition does not occur in `states`, you can set `PSEUDOTR(i, j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

Pseudotransitions and Pseudoemissions

If the probability of a specific transition or emission is very low, the transition might never occur in the sequence `states`, or the emission might never occur in the sequence `seq`. In either case, the algorithm returns a probability of 0 for the given transition or emission in `TRANS` or `EMIS`. You can compensate for the absence of transition with the 'Pseudotransitions' and 'Pseudoemissions' arguments. The simplest way to do this is to set the corresponding entry of `PSEUDOE` or `PSEUDOTR` to 1. For example, if the transition $i \rightarrow j$ does not occur in `states`, set `PSEUDOTR(i, j) = 1`. This forces `TRANS(i, j)` to be positive. If you have an estimate for the expected number of transitions $i \rightarrow j$ in a sequence of the same length as `states`, and the actual number of transitions $i \rightarrow j$ that occur in `seq` is substantially less than what you expect, you can set `PSEUDOTR(i, j)` to the expected number. This increases the value of `TRANS(i, j)`. For transitions that do occur in `states` with the frequency you expect, set the corresponding entry of `PSEUDOTR` to 0, which does not increase the corresponding entry of `TRANS`.

If you do not know the sequence of states, use `hmmtrain` to estimate the model parameters.

Examples

```
trans = [0.95,0.05; 0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(1000,trans,emis);
[estimateTR,estimateE] = hmestimate(seq,states);
```

hmmgenerate

Hidden Markov model states and emissions

Syntax

```
[seq,states] = hmmgenerate(len,TRANS,EMIS)
hmmgenerate(...,'Symbols',SYMBOLS)
hmmgenerate(...,'Statenames',STATENAMES)
```

Description

[seq,states] = hmmgenerate(len,TRANS,EMIS) takes a known Markov model, specified by transition probability matrix TRANS and emission probability matrix EMIS, and uses it to generate

- A random sequence `seq` of emission symbols
- A random sequence `states` of states

The length of both `seq` and `states` is `len`. $\text{TRANS}(i, j)$ is the probability of transition from state `i` to state `j`. $\text{EMIS}(k, l)$ is the probability that symbol `l` is emitted from state `k`.

Note The function `hmmgenerate` begins with the model in state 1 at step 0, prior to the first emission. The model then makes a transition to state i_1 , with probability T_{1i_1} , and generates an emission a_{k_1} with probability $E_{i_1k_1}$. `hmmgenerate` returns i_1 as the first entry of `states`, and a_{k_1} as the first entry of `seq`.

`hmmgenerate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

`hmmgenerate(...,'Statenames',STATENAMES)` specifies the names of the states. STATENAMES can be a numeric array or a cell array of the names of the states. The default state names are 1 through M, where M is the number of states.

Since the model always begins at state 1, whose transition probabilities are in the first row of TRANS, in the following example, the first entry of the output `states` is be 1 with probability 0.95 and 2 with probability 0.05.

Examples

```
trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis)
[seq,states] = hmmgenerate(100,trans,emis,...
    'Symbols',{'one','two','three','four','five','six'},...
    'Statenames',{'fair';'loaded'})
```

See Also

`hmmviterbi` | `hmmdecode` | `hmmestimate` | `hmmtrain`

Introduced before R2006a

hmmtrain

Hidden Markov model parameter estimates from emissions

Syntax

```
[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS)
hmmtrain(...,'Algorithm',algorithm)
hmmtrain(...,'Symbols',SYMBOLS)
hmmtrain(...,'Tolerance',tol)
hmmtrain(...,'Maxiterations',maxiter)
hmmtrain(...,'Verbose',true)
hmmtrain(...,'Pseudoemissions',PSEUDOE)
hmmtrain(...,'Pseudotransitions',PSEUDOTR)
```

Description

[ESTTR,ESTEMIT] = `hmmtrain(seq,TRGUESS,EMITGUESS)` estimates the transition and emission probabilities for a hidden Markov model using the Baum-Welch algorithm. `seq` can be a row vector containing a single sequence, a matrix with one row per sequence, or a cell array with each cell containing a sequence. `TRGUESS` and `EMITGUESS` are initial estimates of the transition and emission probability matrices. `TRGUESS(i,j)` is the estimated probability of transition from state `i` to state `j`. `EMITGUESS(i,k)` is the estimated probability that symbol `k` is emitted from state `i`.

`hmmtrain(...,'Algorithm',algorithm)` specifies the training algorithm. *algorithm* can be either 'BaumWelch' or 'Viterbi'. The default algorithm is 'BaumWelch'.

`hmmtrain(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmtrain(...,'Tolerance',tol)` specifies the tolerance used for testing convergence of the iterative estimation process. The default tolerance is `1e-4`.

`hmmtrain(...,'Maxiterations',maxiter)` specifies the maximum number of iterations for the estimation process. The default maximum is `100`.

`hmmtrain(..., 'Verbose', true)` returns the status of the algorithm at each iteration.

`hmmtrain(..., 'Pseudoemissions', PSEUDOE)` specifies pseudocount emission values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. `PSEUDOE` should be a matrix of size m -by- n , where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the $i \rightarrow k$ emission does not occur in `seq`, you can set `PSEUDOE(i, k)` to be a positive number representing an estimate of the expected number of such emissions in the sequence `seq`.

`hmmtrain(..., 'Pseudotransitions', PSEUDOTR)` specifies pseudocount transition values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. `PSEUDOTR` should be a matrix of size m -by- m , where m is the number of states in the hidden Markov model. If the $i \rightarrow j$ transition does not occur in `states`, you can set `PSEUDOTR(i, j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

If you know the states corresponding to the sequences, use `hmmestimate` to estimate the model parameters.

Tolerance

The input argument `'tolerance'` controls how many steps the `hmmtrain` algorithm executes before the function returns an answer. The algorithm terminates when all of the following three quantities are less than the value that you specify for `tolerance`:

- The log likelihood that the input sequence `seq` is generated by the currently estimated values of the transition and emission matrices
- The change in the norm of the transition matrix, normalized by the size of the matrix
- The change in the norm of the emission matrix, normalized by the size of the matrix

The default value of `'tolerance'` is `1e-6`. Increasing the tolerance decreases the number of steps the `hmmtrain` algorithm executes before it terminates.

maxiterations

The maximum number of iterations, `'maxiterations'`, controls the maximum number of steps the algorithm executes before it terminates. If the algorithm

executes `maxiter` iterations before reaching the specified tolerance, the algorithm terminates and the function returns a warning. If this occurs, you can increase the value of `'maxiterations'` to make the algorithm reach the desired tolerance before terminating.

Examples

```
trans = [0.95,0.05;  
         0.10,0.90];  
emis = [1/6, 1/6, 1/6, 1/6, 1/6, 1/6;  
        1/10, 1/10, 1/10, 1/10, 1/10, 1/2];  
  
seq1 = hmmgenerate(100,trans,emis);  
seq2 = hmmgenerate(200,trans,emis);  
seqs = {seq1,seq2};  
[estTR,estE] = hmmtrain(seqs,trans,emis);
```

hmmviterbi

Hidden Markov model most probable state path

Syntax

```
STATES = hmmviterbi(seq,TRANS,EMIS)
hmmviterbi(...,'Symbols',SYMBOLS)
hmmviterbi(...,'Statenames',STATENAMES)
```

Description

`STATES = hmmviterbi(seq,TRANS,EMIS)` given a sequence, `seq`, calculates the most likely path through the hidden Markov model specified by transition probability matrix, `TRANS`, and emission probability matrix `EMIS`. `TRANS(i,j)` is the probability of transition from state `i` to state `j`. `EMIS(i,k)` is the probability that symbol `k` is emitted from state `i`.

Note The function `hmmviterbi` begins with the model in state 1 at step 0, prior to the first emission. `hmmviterbi` computes the most likely path based on the fact that the model begins in state 1.

`hmmviterbi(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmviterbi(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array or a cell array of the names of the states. The default state names are 1 through `M`, where `M` is the number of states.

Examples

```
trans = [0.95,0.05;
         0.10,0.90];
```

```
emis = [1/6 1/6 1/6 1/6 1/6 1/6;  
        1/10 1/10 1/10 1/10 1/10 1/2];  
  
[seq,states] = hmmgenerate(100,trans,emis);  
estimatedStates = hmmviterbi(seq,trans,emis);  
  
[seq,states] = ...  
    hmmgenerate(100,trans,emis,...  
                'Statenames',{'fair';'loaded'});  
estimatedStates = ...  
    hmmviterbi(seq,trans,emis,...  
                'Statenames',{'fair';'loaded'});
```

Introduced before R2006a

horzcat

Class: dataset

Horizontal concatenation for dataset arrays

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = horzcat(ds1, ds2, ...)
```

Description

`ds = horzcat(ds1, ds2, ...)` horizontally concatenates the dataset arrays `ds1`, `ds2`, You may concatenate dataset arrays that have duplicate variable names, however, the variables must contain identical data, and `horzcat` includes only one copy of the variable in the output dataset.

Observation names for all dataset arrays that have them must be identical except for order. `horzcat` concatenates by matching observation names when present, or by position for datasets that do not have observation names.

See Also

`cat` | `vertcat`

hougen

Hougen-Watson model

Syntax

```
yhat = hougen(beta, x)
```

Description

`yhat = hougen(beta, x)` returns the predicted values of the reaction rate, `yhat`, as a function of the vector of parameters, `beta`, and the matrix of data, `X`. `beta` must have 5 elements and `X` must have three columns.

`hougen` is a utility function for `rsmdemo`.

The model form is:

$$\hat{y} = \frac{\beta_1 x_2 - x_3 / \beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}$$

`rsmdemo`

Introduced before R2006a

hygecdf

Hypergeometric cumulative distribution function

Syntax

```
hygecdf(x,M,K,N)
hygecdf(x,M,K,N,'upper')
```

Description

`hygecdf(x,M,K,N)` computes the hypergeometric cdf at each of the values in `x` using the corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. Vector or matrix inputs for `x`, `M`, `K`, and `N` must all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

`hygecdf(x,M,K,N,'upper')` returns the complement of the hypergeometric cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The hypergeometric cdf is

$$p = F(x | M, K, N) = \sum_{i=0}^x \frac{\binom{K}{i} \binom{M-K}{N-i}}{\binom{M}{N}}$$

The result, p , is the probability of drawing up to x of a possible K items in N drawings without replacement from a group of M objects.

Examples

Compute Hypergeometric Distribution CDF

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing zero to two defective floppies if you select 10 at random?

```
p = hygecdf(2,100,20,10)
```

```
p =
```

```
0.6812
```

Extended Capabilities

C/C++ Code Generation

Introduced before R2006a

hygeinv

Hypergeometric inverse cumulative distribution function

Syntax

```
hygeinv(P,M,K,N)
```

Description

`hygeinv(P,M,K,N)` returns the smallest integer X such that the hypergeometric cdf evaluated at X equals or exceeds P . You can think of P as the probability of observing X defective items in N drawings without replacement from a group of M items where K are defective.

Examples

Suppose you are the Quality Assurance manager for a floppy disk manufacturer. The production line turns out floppy disks in batches of 1,000. You want to sample 50 disks from each batch to see if they have defects. You want to accept 99% of the batches if there are no more than 10 defective disks in the batch. What is the maximum number of defective disks should you allow in your sample of 50?

```
x = hygeinv(0.99,1000,10,50)
x =
    3
```

What is the median number of defective floppy disks in samples of 50 disks from batches with 10 defective disks?

```
x = hygeinv(0.50,1000,10,50)
x =
    0
```

Extended Capabilities

Introduced before R2006a

hygepdf

Hypergeometric probability density function

Syntax

$Y = \text{hygepdf}(X, M, K, N)$

Description

$Y = \text{hygepdf}(X, M, K, N)$ computes the hypergeometric pdf at each of the values in X using the corresponding size of the population, M , number of items with the desired characteristic in the population, K , and number of samples drawn, N . X , M , K , and N can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The parameters in M , K , and N must all be positive integers, with $N \leq M$. The values in X must be less than or equal to all the parameter values.

The hypergeometric pdf is

$$y = f(x | M, K, N) = \frac{\binom{K}{x} \binom{M-K}{N-x}}{\binom{M}{N}}$$

The result, y , is the probability of drawing exactly x of a possible K items in n drawings without replacement from a group of M objects.

Examples

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing 0 through 5 defective floppy disks if you select 10 at random?

```
p = hygepdf(0:5,100,20,10)
p =
    0.0951    0.2679    0.3182    0.2092    0.0841    0.0215
```

Extended Capabilities

pdf | hygecdf | hygeinv | hygestat | hygernd

Introduced before R2006a

hygernd

Hypergeometric random numbers

Syntax

```
R = hygernd(M,K,N)
R = hygernd(M,K,N,m,n,...)
R = hygernd(M,K,N,[m,n,...])
```

Description

`R = hygernd(M,K,N)` generates random numbers from the hypergeometric distribution with corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. `M`, `K`, and `N` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `R`. A scalar input for `M`, `K`, or `N` is expanded to a constant array with the same dimensions as the other inputs.

`R = hygernd(M,K,N,m,n,...)` or `R = hygernd(M,K,N,[m,n,...])` generates an `m-by-n-by-...` array. The `M`, `K`, `N` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
numbers = hygernd(1000,40,50)
numbers =
    1
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

Introduced before R2006a

hygestat

Hypergeometric mean and variance

Syntax

```
[MN,V] = hygestat(M,K,N)
```

Description

`[MN,V] = hygestat(M,K,N)` returns the mean of and variance for the hypergeometric distribution with corresponding size of the population, M , number of items with the desired characteristic in the population, K , and number of samples drawn, N . Vector or matrix inputs for M , K , and N must have the same size, which is also the size of MN and V . A scalar input for M , K , or N is expanded to a constant matrix with the same dimensions as the other inputs.

The mean of the hypergeometric distribution with parameters M , K , and N is NK/M , and the variance is $NK(M-K)(M-N) / [M^2(M-1)]$.

Examples

The hypergeometric distribution approaches the binomial distribution, where $p = K/M$, as M goes to infinity.

```
[m,v] = hygestat(10.^(1:4),10.^(0:3),9)
m =
    0.9000    0.9000    0.9000    0.9000
v =
    0.0900    0.7445    0.8035    0.8094
```

```
[m,v] = binostat(9,0.1)
m =
    0.9000
v =
    0.8100
```

Extended Capabilities

hyperparameters

Variable descriptions for optimizing a fit function

Syntax

```
VariableDescriptions = hyperparameters(FitFcnName,predictors,  
response)
```

```
VariableDescriptions = hyperparameters(FitFcnName,predictors,  
response,LearnerType)
```

Description

`VariableDescriptions = hyperparameters(FitFcnName,predictors, response)` returns the default variables for the given fit function. These are the variables that apply when you set the `OptimizeHyperparameters` name-value pair to `'auto'`.

`VariableDescriptions = hyperparameters(FitFcnName,predictors, response,LearnerType)` returns the variables for an ensemble fit with specified learner type. This syntax applies when `FitFcnName` is `'fitcecoc'`, `'fitcensemble'`, or `'fitrensemble'`.

Examples

Obtain Default Hyperparameters

Obtain the default hyperparameters for the `fitcsvm` classifier.

Load the `ionosphere` data.

```
load ionosphere
```

Obtain the hyperparameters.

```
VariableDescriptions = hyperparameters('fitcsvm',X,Y);
```

Examine all the hyperparameters.

```
for ii = 1:length(VariableDescriptions)
    disp(ii),disp(VariableDescriptions(ii))
end
```

1

optimizableVariable with properties:

```
    Name: 'BoxConstraint'
    Range: [1.0000e-03 1000]
    Type: 'real'
    Transform: 'log'
    Optimize: 1
```

2

optimizableVariable with properties:

```
    Name: 'KernelScale'
    Range: [1.0000e-03 1000]
    Type: 'real'
    Transform: 'log'
    Optimize: 1
```

3

optimizableVariable with properties:

```
    Name: 'KernelFunction'
    Range: {'gaussian' 'linear' 'polynomial'}
    Type: 'categorical'
    Transform: 'none'
    Optimize: 0
```

4

optimizableVariable with properties:

```
    Name: 'PolynomialOrder'
    Range: [2 4]
    Type: 'integer'
    Transform: 'none'
    Optimize: 0
```

5

```
optimizableVariable with properties:
```

```
    Name: 'Standardize'  
    Range: {'true' 'false'}  
    Type: 'categorical'  
    Transform: 'none'  
    Optimize: 0
```

Change the `PolynomialOrder` hyperparameter to have a wider range and to be used in an optimization.

```
VariableDescriptions(4).Range = [2,5];  
VariableDescriptions(4).Optimize = true;  
disp(VariableDescriptions(4))
```

```
optimizableVariable with properties:
```

```
    Name: 'PolynomialOrder'  
    Range: [2 5]  
    Type: 'integer'  
    Transform: 'none'  
    Optimize: 1
```

Obtain Ensemble Hyperparameters

Obtain the default hyperparameters for the `fitensemble` ensemble regression function.

Load the `carsmall` data.

```
load carsmall
```

Use `Horsepower` and `Weight` as predictor variables, and `MPG` as the response variable.

```
X = [Horsepower Weight];  
Y = MPG;
```

Obtain the default hyperparameters for a `Tree` learner.

```
VariableDescriptions = hyperparameters('fitensemble',X,Y,'Tree');
```

Examine all the hyperparameters.

```
for ii = 1:length(VariableDescriptions)
    disp(ii),disp(VariableDescriptions(ii))
end
```

1

optimizableVariable with properties:

```
    Name: 'Method'
    Range: {'Bag' 'LSBoost'}
    Type: 'categorical'
    Transform: 'none'
    Optimize: 1
```

2

optimizableVariable with properties:

```
    Name: 'NumLearningCycles'
    Range: [10 500]
    Type: 'integer'
    Transform: 'log'
    Optimize: 1
```

3

optimizableVariable with properties:

```
    Name: 'LearnRate'
    Range: [1.0000e-03 1]
    Type: 'real'
    Transform: 'log'
    Optimize: 1
```

4

optimizableVariable with properties:

```
    Name: 'MinLeafSize'
    Range: [1 50]
    Type: 'integer'
    Transform: 'log'
    Optimize: 1
```

5

```
optimizableVariable with properties:
```

```
    Name: 'MaxNumSplits'
    Range: [1 99]
    Type: 'integer'
    Transform: 'log'
    Optimize: 0
```

```
6
```

```
optimizableVariable with properties:
```

```
    Name: 'NumVariablesToSample'
    Range: [1 2]
    Type: 'integer'
    Transform: 'none'
    Optimize: 0
```

Change the `MaxNumSplits` hyperparameter to have a wider range and to be used in an optimization.

```
VariableDescriptions(5).Range = [1,200];
VariableDescriptions(5).Optimize = true;
disp(VariableDescriptions(5))
```

```
optimizableVariable with properties:
```

```
    Name: 'MaxNumSplits'
    Range: [1 200]
    Type: 'integer'
    Transform: 'log'
    Optimize: 1
```

Input Arguments

FitFcnName — Name of fitting function

```
'fitcdiscr' | 'fitcecoc' | 'fitcknn' | 'fitcensemble' | 'fitclinear'
| 'fitcnb' | 'fitcsvm' | 'fitctree' | 'fitrensemble' | 'fitrgp' |
'fitrlinear' | 'fitrsvm' | 'fitrtree'
```

Name of fitting function, specified as one of the listed classification or regression fit function names.

If `FitFcnName` is `'fitcecoc'`, `'fitcensemble'`, or `'fitrensemble'`, then also specify the learner type in the `LearnerType` argument.

Example: `'fitctree'`

Data Types: `char`

predictors — Predictor data

matrix with D predictor columns | table with D predictor columns

Predictor data, specified as a matrix with D predictor columns or as a table with D predictor columns, where D is the number of predictors.

Example: X

Data Types: `double` | `logical` | `char` | `table` | `cell` | `categorical` | `datetime`

response — Class labels or numeric response

grouping variable | scalar

Class labels or numeric response, specified as a grouping variable (see “Grouping Variables” on page 2-58) or as a scalar.

Example: Y

Data Types: `single` | `double` | `logical` | `char` | `cell`

LearnerType — Learner type for ensemble fit

`'Discriminant'` | `'KNN'` | `'Linear'` | `'SVM'` | `'Tree'` | template of a listed learner

Learner type for ensemble fit, specified as `'Discriminant'`, `'KNN'`, `'Linear'`, `'SVM'`, `'Tree'`, or a template of a listed learner. Use this argument when `FitFcnName` is `'fitcecoc'`, `'fitcensemble'`, or `'fitrensemble'`.

For `'fitcensemble'` you can use only `'Discriminant'`, `'KNN'`, `'Tree'`, or an associated template.

For `'fitrensemble'`, you can use only `'Tree'` or `templateTree`.

Example: `'Tree'`

Data Types: `char`

Output Arguments

VariableDescriptions — Variable descriptions

vector of `optimizableVariable` objects

Variable descriptions, returned as a vector of `optimizableVariable` objects. The variables have their default parameters set, such as range and variable type. All eligible variables exist in the descriptions, but the variables unused in the 'auto' setting have their `Optimize` property set to `false`. You can update the variables by using dot notation, as shown in “Examples” on page 29- .

Introduced in R2016b

icdf

Inverse cumulative distribution functions

Syntax

```
x = icdf('name',y,A)
x = icdf('name',y,A,B)
x = icdf('name',y,A,B,C)
x = icdf('name',y,A,B,C,D)
```

```
x = icdf(pd,y)
```

Description

`x = icdf('name',y,A)` returns the inverse cumulative distribution function (icdf) for the one-parameter distribution family specified by `'name'`, evaluated at the probability values in `y`. `A` contains the parameter value for the distribution.

`x = icdf('name',y,A,B)` returns the icdf for the two-parameter distribution family specified by `'name'`, evaluated at the probability values in `y`. `A` and `B` contain the parameter values for the distribution.

`x = icdf('name',y,A,B,C)` returns the icdf for the three-parameter distribution family specified by `'name'`, evaluated at the probability values in `y`. `A`, `B`, and `C` contain the parameter values for the distribution.

`x = icdf('name',y,A,B,C,D)` returns the icdf for the four-parameter distribution family specified by `'name'`, evaluated at the probability values in `y`. `A`, `B`, `C`, and `D` contain the parameter values for the distribution.

`x = icdf(pd,y)` returns the inverse cumulative distribution function of the probability distribution object, `pd`, evaluated at the probability values in `y`.

Examples

Compute the Normal Distribution icdf

Create a standard normal distribution object with the mean, μ , equal to 0 and the standard deviation, σ , equal to 1.

```
mu = 0;
sigma = 1;
pd = makedist('Normal',mu,sigma);
```

Define the input vector y to contain the probability values at which to calculate the icdf.

```
y = [0.1,0.25,0.5,0.75,0.9];
```

Compute the icdf values for the standard normal distribution at the values in y .

```
x = icdf(pd,y)
```

```
x =
```

```
-1.2816   -0.6745         0    0.6745    1.2816
```

Each value in x corresponds to a value in the input vector y . For example, at the value y equal to 0.9, the corresponding icdf value x is equal to 1.2816.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the `icdf` function and specify a standard normal distribution using the same parameter values for μ and σ .

```
x2 = icdf('Normal',y,mu,sigma)
```

```
x2 =
```

```
-1.2816   -0.6745         0    0.6745    1.2816
```

The icdf values are the same as those computed using the probability distribution object.

Compute the Poisson Distribution icdf

Create a Poisson distribution object with the rate parameter, λ , equal to 2.

```
lambda = 2;  
pd = makedist('Poisson',lambda);
```

Define the input vector y to contain the probability values at which to calculate the icdf.

```
y = [0.1,0.25,0.5,0.75,0.9];
```

Compute the icdf values for the Poisson distribution at the values in y .

```
x = icdf(pd,y)
```

```
x =
```

```
    0     1     2     3     4
```

Each value in x corresponds to a value in the input vector y . For example, at the value y equal to 0.9, the corresponding icdf value x is equal to 4.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the `icdf` function and specify a Poisson distribution using the same value for the rate parameter λ .

```
x2 = icdf('Poisson',y,lambda)
```

```
x2 =
```

```
    0     1     2     3     4
```

The icdf values are the same as those computed using the probability distribution object.

Input Arguments

'name' — Probability distribution name
valid probability distribution name

Probability distribution name, specified as one of the following.

name	Distribution	Input Parameter A	Input Parameter B	Input Parameter C	Input Parameter D
'Beta '	“Beta Distribution” on page B-4	α : first shape parameter	b : second shape parameter	—	—

y — Probability values at which to evaluate icdf

scalar value | array of scalar values

Probability values at which to evaluate the icdf, specified as a scalar value, or an array of scalar values.

- If x is a scalar value, and if you specify distribution parameters A , B , C , or D as arrays, then `cdf` expands x into a constant array of the same size as the parameters.
- If x is an array, and if you specify distribution parameters A , B , C , or D as arrays, then x , A , B , C , and D must all be the same size.

Example: [0.1,0.25,0.5,0.75,0.9]

Data Types: single | double

A — First probability distribution parameter

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value, or an array of scalar values.

If x and A are arrays, they must be the same size. If x is a scalar, then `cdf` expands it into a constant matrix the same size as A . If A is a scalar, then `cdf` expands it into a constant matrix the same size as x .

Data Types: single | double

B — Second probability distribution parameter

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value, or an array of scalar values.

If x , A , and B are arrays, they must be the same size. If x is a scalar, then `cdf` expands it into a constant matrix the same size as A and B . If A or B are scalars, then `cdf` expands them into constant matrices the same size as x .

Data Types: single | double

C — Third probability distribution parameter

scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value, or an array of scalar values.

If x , A , B , and C are arrays, they must be the same size. If x is a scalar, then `cdf` expands it into a constant matrix the same size as A , B , and C . If any of A , B or C are scalars, then `cdf` expands them into constant matrices the same size as x .

Data Types: `single` | `double`

D — Fourth probability distribution parameter

scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value, or an array of scalar values.

If x , A , B , C , and D are arrays, they must be the same size. If x is a scalar, then `cdf` expands it into a constant array the same size as A , B , C , and D . If any of A , B , C , or D are scalars, then `cdf` expands them into constant matrices the same size as x .

Data Types: `single` | `double`

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
<code>distributionFitter</code>	Fit a probability distribution object to sample data using the interactive Distribution Fitting app.
<code>paretotails</code>	Create a Pareto tails object.

Output Arguments

x — Inverse cumulative distribution function

array

Inverse cumulative distribution function of the specified probability distribution, returned as an array.

- If you specify distribution parameters A, B, C, or D, then **x** is the common size of **y**, A, B, C, and D, after any necessary scalar expansion.
- If you specify a probability distribution object, **pd**, then **x** has the same dimensions as **y**.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Topics

“Working with Probability Distributions” on page 5-3

Introduced before R2006a

icdf

Class: `piecwisedistribution`

Inverse cumulative distribution function for piecewise distribution

Syntax

```
X = icdf(obj,P)
```

Description

`X = icdf(obj,P)` returns an array `X` of values of the inverse cumulative distribution function for the piecewise distribution object `obj`, evaluated at the values in the array `P`.

Examples

Fit Pareto tails to a *t* distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)
p =
    0.1000
    0.9000
q =
   -1.7766
    1.8432

icdf(obj,p)
ans =
   -1.7766
    1.8432
```

See Also

`paretotails` | `cdf`

icdf

Class: ProbDistUnivKernel

Return inverse cumulative distribution function (ICDF) for ProbDistUnivKernel object

Syntax

$Y = \text{icdf}(PD, P)$

Description

$Y = \text{icdf}(PD, P)$ returns Y , an array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivKernel object PD , evaluated at values in P .

Input Arguments

PD	An object of the class ProbDistUnivKernel.
P	A numeric array of values from 0 to 1 where you want to evaluate the ICDF.

Output Arguments

Y	An array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivKernel object PD .
-----	--

See Also

icdf

icdf

Class: ProbDistUnivParam

Return inverse cumulative distribution function (ICDF) for ProbDistUnivParam object

Syntax

$Y = \text{icdf}(PD, P)$

Description

$Y = \text{icdf}(PD, P)$ returns Y , an array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivParam object PD , evaluated at values in P .

Input Arguments

PD	An object of the class ProbDistUnivParam.
P	A numeric array of values from 0 to 1 where you want to evaluate the ICDF.

Output Arguments

Y	An array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivParam object PD .
-----	---

See Also

icdf

icdf

Class: prob.TruncatableDistribution

Package: prob

Inverse cumulative distribution function of probability distribution object

Syntax

```
y = icdf(pd,prob)
```

Description

`y = icdf(pd,prob)` returns the inverse cumulative distribution function (icdf) values of the probability distribution `pd` at the probabilities in `prob`.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

prob — Probabilities

array of scalar values in the range [0,1]

Probabilities at which to compute the icdf, specified as an array of scalar values in the range [0,1]. For example, specifying `[.25 .5 .75]` returns a vector containing three icdf values corresponding to these probabilities.

Data Types: `single` | `double`

Output Arguments

y – Inverse cumulative distribution function

array

Inverse cumulative distribution function (icdf) values of the specified probability distribution, evaluated at the probabilities in `prob`, returned as an array. `y` has the same dimensions as `x`.

Examples

Compute Standard Normal Critical Values

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Determine the critical values at the 5% significance level for a test statistic with a standard normal distribution, by computing the upper and lower 2.5% values.

```
y = icdf(pd, [.025, .975])
```

```
y =
```

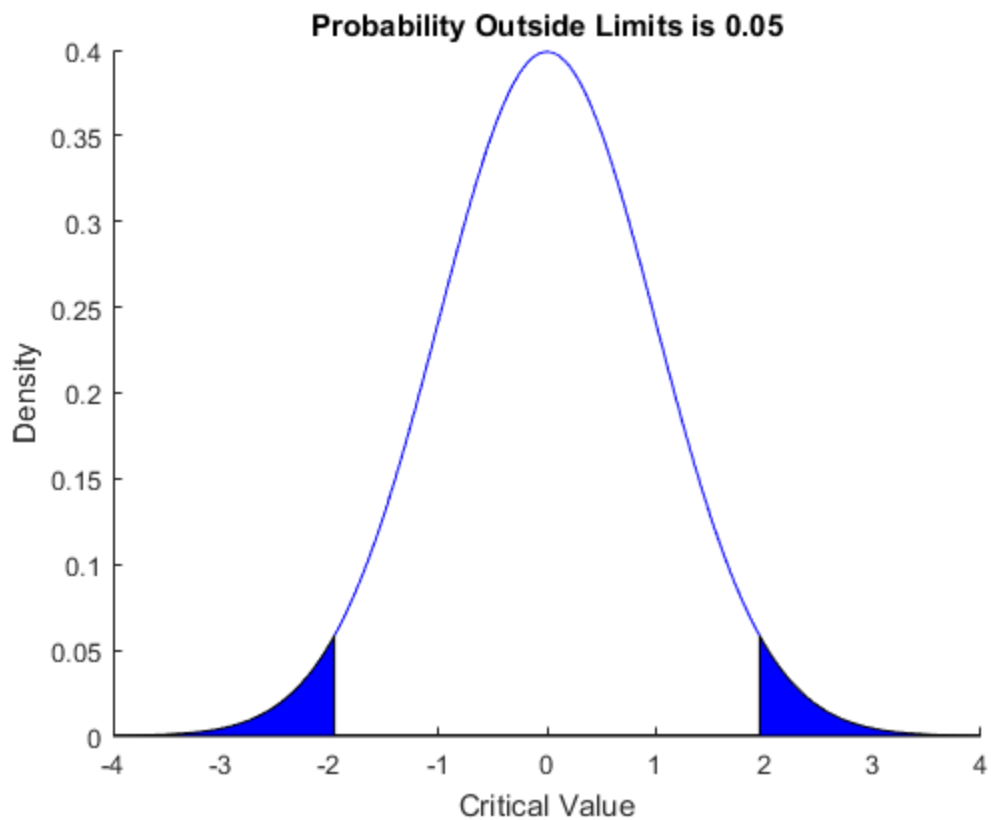

```
-1.9600    1.9600
```

inconsistent

Inconsistency coefficient

Syntax

`Y = inconsistent(Z)`
`Y = inconsistent(Z,d)`

Description

`Y = inconsistent(Z)` computes the inconsistency coefficient for each link of the hierarchical cluster tree `Z`, where `Z` is an $(m-1)$ -by-3 matrix generated by the `linkage` function. The inconsistency coefficient characterizes each link in a cluster tree by comparing its height with the average height of other links at the same level of the hierarchy. The higher the value of this coefficient, the less similar the objects connected by the link.

`Y = inconsistent(Z,d)` computes the inconsistency coefficient for each link in the hierarchical cluster tree `Z` to depth `d`, where `d` is an integer denoting the number of levels of the cluster tree that are included in the calculation. By default, `d=2`.

The output, `Y`, is an $(m-1)$ -by-4 matrix formatted as follows.

Column	Description
1	Mean of the heights of all the links included in the calculation.
2	Standard deviation of the heights of all the links included in the calculation.
3	Number of links included in the calculation.
4	Inconsistency coefficient.

For each link, k , the inconsistency coefficient is calculated as:

$$Y(k,4) = (z(k,3) - Y(k,1)) / Y(k,2)$$

For leaf nodes, nodes that have no further nodes under them, the inconsistency coefficient is set to 0.

Examples

Compute Inconsistency Coefficient

Create the sample data.

```
X = gallery('uniformdata',[10 2],12);  
Y = pdist(X);
```

Generate the hierarchical cluster tree.

```
Z = linkage(Y,'single');
```

Generate a dendrogram plot of the hierarchical cluster tree.

```
dendrogram(Z)
```

Compute the inconsistency coefficient for each link in the cluster tree Z to depth 3.

$W = \text{inconsistent}(Z, 3)$

$W =$

0.1313	0	1.0000	0
0.1386	0	1.0000	0

Introduced before R2006a

increaseB

Class: clustering.evaluation.GapEvaluation

Package: clustering.evaluation

Increase reference data sets

Syntax

```
eva_out = increaseB(eva,nref)
```

Description

`eva_out = increaseB(eva,nref)` returns a gap criterion clustering evaluation object `eva_out` that uses the same evaluation criteria as the input object `eva` and an additional number of reference data sets as specified by `nref`.

Input Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

nref — Number of additional reference data sets

positive integer value

Number of additional reference data sets, specified as a positive integer value.

Output Arguments

eva_out — Updated clustering evaluation data

clustering evaluation object

Updated clustering evaluation data, returned as a gap criterion clustering evaluation object. `eva_out` contains evaluation data obtained using the reference data sets from the input object `eva` plus a number of additional reference data sets as specified in `nref`.

`increaseB` updates the `B` property of the input object `eva` to reflect the increase in the number of reference data sets used to compute the gap criterion values. `increaseB` also updates the `CriterionValues` property with gap criterion values computed using the total number of reference data sets. `increaseB` might also update the `OptimalK` and `OptimalY` properties to reflect the optimal number of clusters and optimal clustering solution as determined using the total number of reference data sets. Additionally, `increaseB` might also update the `LogW`, `ExpectedLogW`, `StdLogW`, and `SE` properties.

Examples

Evaluate Clustering Solutions Using Additional Reference Data

Create a gap clustering evaluation object using `evalclusters`, then use `increaseB` to increase the number of reference data sets used to compute the gap criterion values.

Load the sample data.

```
load fisheriris
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Cluster the flower measurement data using `kmeans`, and use the gap criterion to evaluate proposed solutions of one through five clusters. Use 50 reference data sets.

```
eva = evalclusters(meas, 'kmeans', 'gap', 'klist', 1:5, 'B', 50)
```

```
eva =
```

```
GapEvaluation with properties:
```

```
NumObservations: 150
  InspectedK: [1 2 3 4 5]
CriterionValues: [0.0870 0.5822 0.8766 1.0007 1.0465]
  OptimalK: 4
```

The clustering evaluation object `eva` contains data on each proposed clustering solution. The returned results indicate that the optimal number of clusters is five.

The value of the `B` property of `eva` shows 50 reference data sets.

```
eva.B
```

```
ans =
```

```
50
```

Increase the number of reference data sets by 50, for a total of 100 sets.

```
eva = increaseB(eva,50)
```

```
eva =
```

```
GapEvaluation with properties:
```

```
NumObservations: 150
```

```
InspectedK: [1 2 3 4 5]
```

```
CriterionValues: [0.0814 0.5845 0.8736 1.0034 1.0506]
```

```
OptimalK: 4
```

The returned results now indicate that the optimal number of clusters is four.

The value of the `B` property of `eva` now shows 100 reference data sets.

```
eva.B
```

```
ans =
```

```
100
```

`evalclusters`

InputData property

Class: ProbDist

Read-only structure containing information about input data to ProbDist object

Description

`InputData` is a read-only property of the ProbDist class. `InputData` is a structure containing information about input data to a ProbDist object. It includes the following fields:

- `data`
- `cens`
- `freq`

Values

Possible values for the three fields in the structure are any data supplied to the `fitdist` function:

- `data` — Data passed to the `fitdist` function when creating the ProbDist object. This field is empty if the ProbDist object was created without fitting to data, that is by using the ProbDistUnivParam constructor.
- `cens` — The vector supplied with the `'censoring'` parameter when creating the ProbDist object using the `fitdist` function. This field is empty if the ProbDist object was created without fitting to data, that is by using the ProbDistUnivParam constructor.
- `freq` — The vector supplied with the `'frequency'` parameter when creating the ProbDist object using the `fitdist` function. This field is empty if the ProbDist object was created without fitting to data, that is by using the ProbDistUnivParam constructor.

Use this information to view and compare the data supplied to create distributions.

interactionplot

Interaction plot for grouped data

Syntax

```
interactionplot(Y, GROUP)
interactionplot(Y, GROUP, 'varnames', VARNAMES)
[h, AX, bigax] = interactionplot(...)
```

Description

`interactionplot(Y, GROUP)` displays the two-factor interaction plot for the group means of matrix `Y` with groups defined by entries in the cell array `GROUP`. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. If `Y` is a vector, the rows give the means of each entry in the cell array `GROUP`. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or a single-column cell array of character vectors. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The interaction plot is a matrix plot, with the number of rows and columns both equal to the number of grouping variables. The grouping variable names are printed on the diagonal of the plot matrix. The plot at off-diagonal position (i,j) is the interaction of the two variables whose names are given at row diagonal (i,i) and column diagonal (j,j) , respectively.

`interactionplot(Y, GROUP, 'varnames', VARNAMES)` displays the interaction plot with user-specified grouping variable names `VARNAMES`. `VARNAMES` is a character matrix or a cell array of character vectors, one per grouping variable. Default names are 'X1', 'X2',

`[h, AX, bigax] = interactionplot(...)` returns a handle `h` to the figure window, a matrix `AX` of handles to the subplot axes, and a handle `bigax` to the big (invisible) axes framing the subplots.

Examples

Display Interaction Plots

Randomly generate data for a response variable y .

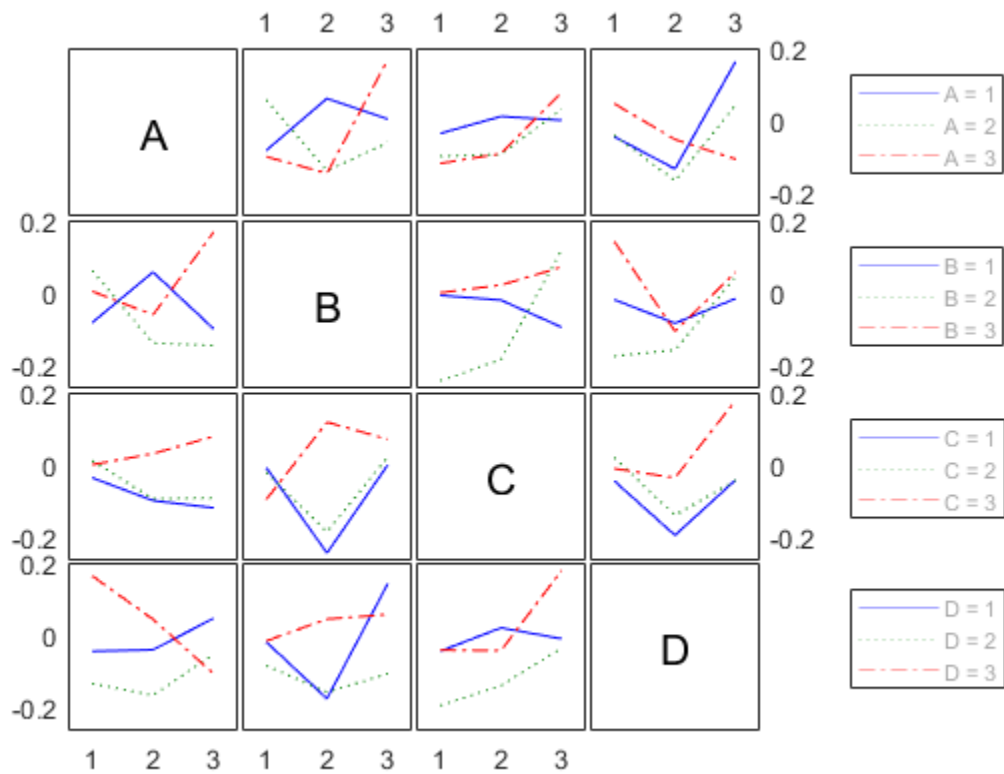

```
rng default; % For reproducibility  
y = randn(1000,1);
```

Randomly generate data for four three-level factors.

```
group = ceil(3*rand(1000,4));
```

Display the interaction plots for the factors and name the factors 'A', 'B', 'C', 'D'.

```
interactionplot(y,group, 'varnames', {'A', 'B', 'C', 'D'})
```

Introduced in R2006b

intersect

Class: dataset

Set intersection for dataset array observations

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = intersect(A,B)
C = intersect(A,B,vars)
C = intersect(A,B,vars,setOrder)
[C,iA,iB] = intersect( __ )
```

Description

`C = intersect(A,B)` for dataset arrays **A** and **B** returns the common set of observations from the two arrays, with repetitions removed. The observations in the dataset array **C** are in sorted order.

`C = intersect(A,B,vars)` returns the set of common observations from the two arrays, considering only the variables specified in **vars**, with repetitions removed. The observations in the dataset array **C** are sorted by those variables.

The values for variables not specified in **vars** for each observation in **C** are taken from the corresponding observations in **A**. If there are multiple observations in **A** that correspond to an observation in **C**, then those values are taken from the first occurrence.

`C = intersect(A,B,vars,setOrder)` returns the observations in **C** in the order specified by **setOrder**.

`[C, iA, iB] = intersect(____)` also returns index vectors `iA` and `iB` such that `C = A(iA, :)` and `C = B(iB, :)`. If there are repeated observations in `A` or `B`, then `intersect` returns the index of the first occurrence. You can use any of the previous input arguments.

Input Arguments

A, B

Input dataset arrays.

vars

Cell array of character vectors containing variable names or a vector of integers containing variable column numbers, indicating the variables in `A` and `B` that `intersect` considers.

Specify `vars` as `[]` to use its default value of all variables.

setOrder

Flag indicating the sorting order for the observations in `C`. The possible values of `setOrder` are:

- | | |
|----------|---|
| 'sorted' | Observations in <code>C</code> are in sorted order (default). |
| 'stable' | Observations in <code>C</code> are in the same order that they appear in <code>A</code> . |

Output Arguments

C

Dataset array with the common set of observations in `A` and `B`, with repetitions removed. `C` is in sorted order (by default), or the order specified by `setOrder`.

iA

Index vector, indicating the observations in `A` that are common to `B`. The vector `iA` contains the index to the first occurrence of any repeated observations in `A`.

iB

Index vector, indicating the observations in **B** that are common to **A**. The vector **iB** contains the index to the first occurrence of any repeated observations in **B**.

Examples

Intersection of Two Dataset Arrays

Navigate to the folder containing sample data, and load sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

A = dataset('XLSFile','hospitalSmall.xlsx');
B = dataset('XLSFile','hospitalSmall.xlsx','Sheet',2);
```

Return the intersection and index vectors.

```
[C,iA,iB] = intersect(A,B);
```

C =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

There is one observation in common between **A** and **B**.

Find the observation in the original dataset arrays.

```
A(iA,:)
```

ans =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

```
B(iB,:)
```

ans =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

prob.InverseGaussianDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Inverse Gaussian probability distribution object

Description

`prob.InverseGaussianDistribution` is an object consisting of parameters, a model description, and sample data for an inverse Gaussian probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitter app.

Construction

`pd = makedist('InverseGaussian')` creates an inverse Gaussian probability distribution object using the default parameter values.

`pd = makedist('InverseGaussian','mu',mu,'lambda',lambda)` creates an inverse Gaussian probability distribution object using the specified parameter values.

Input Arguments

mu — Scale parameter

1 (default) | positive scalar value

Scale parameter for the inverse Gaussian distribution, specified as a positive scalar value.

Data Types: `single` | `double`

lambda — Shape parameter

1 (default) | positive scalar value

Shape parameter for the inverse Gaussian distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Properties

mu — Scale parameter

positive scalar value

Scale parameter for the inverse Gaussian distribution, stored as a positive scalar value.

Data Types: `single` | `double`

lambda — Shape parameter

positive scalar value

Shape parameter for the inverse Gaussian distribution, stored as a positive scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

character vector

Probability distribution name, stored as a character vector. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: single | double

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: single | double

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

Distribution parameter descriptions, stored as a cell array of character vectors. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: logical

ParameterNames — Distribution parameter names

cell array of character vectors

Distribution parameter names, stored as a cell array of character vectors. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative log likelihood of probability distribution object

paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Examples

Create an Inverse Gaussian Distribution Object Using Default Parameters

Create an inverse Gaussian distribution object using the default parameter values.

```
pd = makedist('InverseGaussian')
```

```
pd =  
InverseGaussianDistribution  
  
Inverse Gaussian distribution  
    mu = 1  
    lambda = 1
```

Create an Inverse Gaussian Distribution Object Using Specified Parameters

Create an inverse Gaussian distribution object by specifying parameter values.

```
pd = makedist('InverseGaussian', 'mu', 2, 'lambda', 4)
```

```
pd =  
InverseGaussianDistribution  
  
Inverse Gaussian distribution  
    mu = 2  
    lambda = 4
```

Compute the standard deviation of the distribution.

```
s = std(pd)
```

```
s =
```

```
1.4142
```

Definitions

Inverse Gaussian Distribution

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

The inverse Gaussian distribution uses the following parameters.

Parameter	Description	Support
mu	Scale parameter	$\mu > 0$
lambda	Shape parameter	$\lambda > 0$

The probability density function (pdf) is

$$f(x | \mu, \lambda) = \sqrt{\frac{\lambda}{2\pi x^3}} \exp\left\{-\frac{\lambda}{2\mu^2 x}(x - \mu)^2\right\} ; x > 0.$$

Class Attributes (MATLAB)

Property Attributes (MATLAB)

invpred

Inverse prediction

Syntax

```
X0 = invpred(X,Y,Y0)
[X0,DXLO,DXUP] = invpred(X,Y,Y0)
[X0,DXLO,DXUP] = invpred(X,Y,Y0,name1,val1,name2,val2,...)
```

Description

`X0 = invpred(X,Y,Y0)` accepts vectors `X` and `Y` of the same length, fits a simple regression, and returns the estimated value `X0` for which the height of the line is equal to `Y0`. The output, `X0`, has the same size as `Y0`, and `Y0` can be an array of any size.

`[X0,DXLO,DXUP] = invpred(X,Y,Y0)` also computes 95% inverse prediction intervals. `DXLO` and `DXUP` define intervals with lower bound `X0-DXLO` and upper bound `X0+DXUP`. Both `DXLO` and `DXUP` have the same size as `Y0`.

The intervals are not simultaneous and are not necessarily finite. Some intervals may extend from a finite value to `-Inf` or `+Inf`, and some may extend over the entire real line.

`[X0,DXLO,DXUP] = invpred(X,Y,Y0,name1,val1,name2,val2,...)` specifies optional argument name/value pairs chosen from the following list. Argument names are case insensitive and partial matches are allowed.

Name	Value
'alpha'	A value between 0 and 1 specifying a confidence level of $100 \cdot (1 - \text{alpha})\%$. Default is <code>alpha=0.05</code> for 95% confidence.
'predopt'	Either 'observation', the default value to compute the intervals for <code>X0</code> at which a new observation could equal <code>Y0</code> , or 'curve' to compute intervals for the <code>X0</code> value at which the curve is equal to <code>Y0</code> .

Examples

Inverse Prediction

Generate sample data.

```
x = 4*rand(25,1);  
y = 10 + 5*x + randn(size(x));
```

Make a scatterplot of the data.

```
scatter(x,y)
```

Predict the x value for a given y value of 20.

```
x0 = invpred(x,y,20)
```

```
x0 =
```

```
1.9967
```

Introduced before R2006a

iqr

Interquartile range

Syntax

```
r = iqr(x)
r = iqr(x,dim)
r = iqr(pd)
```

Description

`r = iqr(x)` returns the interquartile range of the values in `x`.

`r = iqr(x,dim)` returns the interquartile range along the dimension of `x` specified by `dim`.

`r = iqr(pd)` returns the interquartile range of the probability distribution, `pd`.

Examples

Compute the Interquartile Range

Generate a 4-by-4 matrix of random data from a normal distribution with parameter values μ equal to 10 and σ equal to 1.

```
rng default % For reproducibility
x = normrnd(10,1,4)
```

```
x =
    10.5377    10.3188    13.5784    10.7254
    11.8339     8.6923    12.7694     9.9369
     7.7412     9.5664     8.6501    10.7147
    10.8622    10.3426    13.0349     9.7950
```

Compute the interquartile range for each column of data.

```
r = iqr(x)
```

```
r =
```

```
    2.2086    1.2013    2.5969    0.8541
```

Compute the interquartile range for each row of data.

```
r2 = iqr(x,2)
```

```
r2 =
```

```
    1.7237  
    2.9870  
    1.9449  
    1.8797
```

Compute the Normal Distribution Interquartile Range

Create a standard normal distribution object with the mean, μ , equal to 0 and the standard deviation, σ , equal to 1.

```
pd = makedist('Normal',0,1);
```

Compute the interquartile range of the standard normal distribution.

```
r = iqr(pd)
```

```
r =
```

```
    1.3490
```

The returned value is the difference between the 75th and the 25th percentile values for the distribution. This is equivalent to computing the difference between the inverse cumulative distribution function (icdf) values at the probabilities y equal to 0.75 and 0.25.

```
r2 = icdf(pd,0.75) - icdf(pd,0.25)
```

```
r2 =
```

```
    1.3490
```

Input Arguments

x — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `single` | `double`

dim — Dimension

1 (default) | positive integer value

Dimension along which the interquartile range is calculated, specified as a positive integer. For example, for a matrix `x`, when `dim` is equal to 1, `iqr` returns the interquartile range for the columns of `x`. When `dim` is equal to 2, `iqr` returns the interquartile range for the rows of `x`. For n -dimensional arrays, `iqr` operates along the first nonsingleton dimension of `X`.

Data Types: `single` | `double`

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
<code>distributionFitter</code>	Fit a probability distribution object to sample data using the interactive Distribution Fitter app.

Output Arguments

r — Interquartile range

scalar value

Interquartile range, returned as a scalar value.

- If you input a vector for x , then r is the difference between the 75th and the 25th percentiles of the sample data contained in x .
- If you input a matrix for x , then r is a row vector containing the difference between the 75th and the 25th percentiles of the sample data contained each column of x .
- If you input a probability distribution, pd , then the value of r is the difference between the values of the 75th and 25th percentile of the probability distribution.

iqr

Class: ProbDistUnivKernel

Return interquartile range (IQR) for ProbDistUnivKernel object

Syntax

$Y = \text{iqr}(PD)$

Description

$Y = \text{iqr}(PD)$ returns Y , the interquartile range for the ProbDistUnivKernel object PD . The interquartile range is the distance between the 75th and 25th percentiles.

Input Arguments

PD An object of the class ProbDistUnivKernel.

Output Arguments

Y The value of the interquartile range for the ProbDistUnivKernel object PD .

iqr

Class: prob.TruncatableDistribution

Package: prob

Interquartile range of probability distribution object

Syntax

```
r = iqr(pd)
```

Description

`r = iqr(pd)` returns the interquartile range `r` of the probability distribution `pd`.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

r — Interquartile range

scalar value

Interquartile range of the probability distribution, returned as a scalar value. The value of `r` is the difference between the values of the 75th and 25th percentile of the probability distribution.

Examples

Interquartile Range of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 75.0083 [73.4321, 76.5846]  
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the interquartile range of the fitted distribution.

```
r = iqr(pd)
```

```
r =
```

```
11.7634
```

The returned result indicates that the difference between the 75th and 25th percentile of the students' grades is 11.7634.

Use `icdf` to determine the 75th and 25th percentiles of the students' grades.

```
y = icdf(pd, [0.25, 0.75])
```

```
y =
```

```
69.1266 80.8900
```

Calculate the difference between the 75th and 25th percentiles. This yields the same result as `iqr`.

```
y(2) - y(1)
```

```
ans =
```

```
11.7634
```

Use `boxplot` to visualize the interquartile range.

```
boxplot(x)
```

The top line of the box shows the 75th percentile, and the bottom line shows the 25th percentile. The center line shows the median, which is the 50th percentile.

isbranch

Class: classregtree

Test node for branch

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitmtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
ib = isbranch(t)
ib = isbranch(t,nodes)
```

Description

`ib = isbranch(t)` returns an n -element logical vector `ib` that is `true` for each branch node and `false` for each leaf node.

`ib = isbranch(t,nodes)` takes a vector `nodes` of node numbers and returns a vector of logical values for the specified nodes.

Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
```

```

4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5 class = virginica
6 if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7 class = virginica
8 class = versicolor
9 class = virginica

```

```
view(t)
```

isempty

Class: dataset

True for empty dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
tf = isempty(A)
```

Description

`tf = isempty(A)` returns true (1) if `A` is an empty dataset and false (0) otherwise. An empty array has no elements, that is `prod(size(A))==0`.

See Also

`size`

islevel

Determine if levels are in nominal or ordinal array

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
tf = islevel(levels,A)
```

Description

`tf = islevel(levels,A)` returns a logical array indicating which of the levels in `levels` correspond to a level in the nominal or ordinal array `A`.

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

levels — Levels to test

character vector | cell array of character vectors | 2-D character matrix

Levels to test, specified as a character vector, cell array of character vectors, or 2-D character matrix.

Data Types: `char` | `cell`

Output Arguments

tf — Logical array

array the same size as `levels`

Logical array, returned as an array the same size as `levels`. `tf` has value 1 (true) where the corresponding element of `levels` is the label of a level in the nominal or ordinal array `A`, even if the level contains no elements. `tf` has value 0 (false) otherwise.

Introduced in R2007a

ismember

Class: dataset

Dataset array elements that are members of set

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
LiA = ismember(A,B)  
LiA = ismember(A,B,vars)  
[LiA,LocB] = ismember( ___ )
```

Description

`LiA = ismember(A,B)` for dataset arrays `A` and `B` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value 1 (true) in the elements that correspond to observations in `A` that are also present in `B`, and 0 (false) otherwise.

`LiA = ismember(A,B,vars)` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value 1 (true) in the elements that correspond to observations in `A` that are also present in `B` for the variables specified in `vars` only, and 0 (false) otherwise.

`[LiA,LocB] = ismember(___)` also returns a vector the same length as `A` containing the index to the first observation in `B` that corresponds to each observation in `A`, or 0 if there is no such observation. You can use any of the previous input arguments.

Input Arguments

A

Query dataset array, containing the observations to be found in B.

B

Set dataset array. When an observation in A is found in B, for all variables or only those variables specified in `vars`, the corresponding element of `LiA` is 1.

`vars`

Cell array of character vectors containing variable names or a vector of integers containing variable column numbers, indicating which variables to match observations on in A and B.

Output Arguments

`LiA`

Vector of logical values the same length as A. `LiA` has value 1 (true) when the corresponding observation in A is present in B. Otherwise, `LiA` has value 0 (false).

If you specify `vars`, `LiA` has value 1 when the corresponding observation in A is present in B for the variables in `vars` only.

`LocB`

Vector the same length as A containing the index to the first observation in B that corresponds to each observation in A, for all variables or only those variables specified in `vars`.

Examples

Find Observations That Are Members of a Dataset Array

Load sample data.

```
load('hospital')
B = hospital(1:50,1:5);
```

This set dataset array, B, has 50 observations on 5 variables.

Specify a query dataset array.

```
rng('default')
rIx = randsample(100,10);
A = hospital(rIx,1:5)
```

A =

ismissing

Class: dataset

Find dataset array elements with missing values

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
I = ismissing(ds)
I = ismissing(ds,Name,Value)
```

Description

`I = ismissing(ds)` returns a logical array that indicates which elements in the dataset array, `ds`, contain a missing value. By default, `ismissing` recognizes NaN as a missing value in numeric variables, ' ' as a missing value in character variables, and <undefined> as a missing value in categorical arrays.

- `ds2 = ds(~any(I,2),:)` creates a new dataset array containing only the complete observations in `ds`.
- `ds2 = ds(:,~any(I,1))` creates a new dataset array containing only the variables from `ds` with no missing values.

`I = ismissing(ds,Name,Value)` returns missing value indices with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ds

dataset array

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'`NumericTreatAsMissing`'

Vector of numeric values to treat as missing value indicators in floating point `ds` variables. `ismissing` always treats a NaN value as a missing value.

Default:

'`StringTreatAsMissing`'

Character vector or cell array of character vectors to treat as missing value indicators in character `ds` variables. `ismissing` always treats ' ' as a missing value.

Output Arguments

`I`

Logical array indicating which elements in `ds` contain a missing value. `I` is the same size as `ds`, with value 1 for elements that contain a missing value.

isvalid

Class: grandstream

Test handle validity

Syntax

```
tf = isvalid(h)
```

Description

`tf = isvalid(h)` performs an element-wise check for validity on the handle elements of `h`. The result is a logical array of the same dimensions as `h`, where each element is the element-wise validity result.

A handle is invalid if it has been deleted or if it is an element of a handle array and has not yet been initialized.

See Also

`delete` | `grandstream`

NumIterations property

Class: gmdistribution

Number of iterations

Description

The number of iterations of the algorithm.

Note: This property applies only to `gmdistribution` objects constructed with `fitgmdist`.

iwishrnd

Inverse Wishart random numbers

Syntax

```
W = wishrnd(Tau,df)
W = wishrnd(Tau,df,DI)
[W,DI] = wishrnd(Tau,df)
```

Description

`W = wishrnd(Tau,df)` generates a random matrix `W` from the inverse Wishart distribution with parameters `Tau` and `df`. The inverse of `W` has the Wishart distribution with covariance matrix `Sigma = inv(Tau)` and with `df` degrees of freedom. `Tau` is a symmetric and positive definite matrix.

`W = wishrnd(Tau,df,DI)` expects `DI` to be the transpose of the inverse of the Cholesky factor of `Tau`, so that `DI' * DI = inv(Tau)`, where `inv` is the MATLAB inverse function. `DI` is lower-triangular and the same size as `Tau`. If you call `wishrnd` multiple times using the same value of `Tau`, it is more efficient to supply `DI` instead of computing it each time.

`[W,DI] = wishrnd(Tau,df)` returns `DI` so you can use it as an input in future calls to `wishrnd`.

Note that different sources use different parametrizations for the inverse Wishart distribution. This function defines the parameter `tau` so that the mean of the output matrix is `Tau / (df - d - 1)` where `d` is the dimension of `Tau`.

Introduced before R2006a

jackknife

Jackknife sampling

Syntax

```
jackstat = jackknife(jackfun,X)
jackstat = jackknife(jackfun,X,Y,...)
jackstat = jackknife(jackfun,...,'Options',option)
```

Description

`jackstat = jackknife(jackfun,X)` draws jackknife data samples from the n -by- p data array `X`, computes statistics on each sample using the function `jackfun`, and returns the results in the matrix `jackstat`. `jackknife` regards each row of `X` as one data sample, so there are n data samples. Each of the n rows of `jackstat` contains the results of applying `jackfun` to one jackknife sample. `jackfun` is a function handle specified with `@`. Row i of `jackstat` contains the results for the sample consisting of `X` with the i th row omitted:

```
s = x;
s(i,:) = [];
jackstat(i,:) = jackfun(s);
```

If `jackfun` returns a matrix or array, then this output is converted to a row vector for storage in `jackstat`. If `X` is a row vector, it is converted to a column vector.

`jackstat = jackknife(jackfun,X,Y,...)` accepts additional arguments to be supplied as inputs to `jackfun`. They may be scalars, column vectors, or matrices. `jackknife` creates each jackknife sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to `jackfun` unchanged. Non-scalar arguments must have the same number of rows, and each jackknife sample omits the same row from these arguments.

`jackstat = jackknife(jackfun,...,'Options',option)` provides an option to perform jackknife iterations in parallel, if the Parallel Computing Toolbox is available. Set `'Options'` as a structure you create with `statset`. `jackknife` uses the following field in the structure:

'UseParallel' If true and if a `parpool` of the Parallel Computing Toolbox is open, use multiple processors to compute jackknife iterations. If the Parallel Computing Toolbox is not installed, or a `parpool` is not open, computation occurs in serial mode. Default is `false`, or serial computation.

Examples

Estimate the bias of the MLE variance estimator of random samples taken from the vector `y` using `jackknife`. The bias has a known formula in this problem, so you can compare the `jackknife` value to this formula.

```
sigma = 5;
y = normrnd(0,sigma,100,1);
m = jackknife(@var, y, 1);
n = length(y);
bias = -sigma^2 / n % known bias formula
jbias = (n - 1)*(mean(m)-var(y,1)) % jackknife bias estimate

bias =
    -0.2500

jbias =
    -0.3378
```

Introduced in R2006a

jbtest

Jarque-Bera test

Syntax

```
h = jbtest(x)
h = jbtest(x,alpha)
h = jbtest(x,alpha,mctol)
[h,p] = jbtest(____)
[h,p,jbstat,critval] = jbtest(____)
```

Description

`h = jbtest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with an unknown mean and variance, using the Jarque-Bera test. The alternative hypothesis is that it does not come from such a distribution. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = jbtest(x,alpha)` returns a test decision for the null hypothesis at the significance level specified by `alpha`.

`h = jbtest(x,alpha,mctol)` returns a test decision based on a p -value computed using a Monte Carlo simulation with a maximum Monte Carlo standard error less than or equal to `mctol`.

`[h,p] = jbtest(____)` also returns the p -value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,jbstat,critval] = jbtest(____)` also returns the test statistic `jbstat` and the critical value `critval` for the test.

Examples

Test for a Normal Distribution

Load the data set.

```
load carbig
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```
h = jbttest(MPG)
```

```
h =
```

```
1
```

The returned value of $h = 1$ indicates that `jbttest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at a Different Significance Level

Load the data set.

```
load carbig
```

Test the null hypothesis that car mileage in miles per gallon (MPG) follows a normal distribution across different makes of cars at the 1% significance level.

```
[h,p] = jbttest(MPG,0.01)
```

```
h =
```

```
1
```

```
p =
```

```
0.0022
```

The returned value of $h = 1$, and the returned P -value less than $\alpha = 0.01$ indicate that `jbttest` rejects the null hypothesis.

Test for a Normal Distribution Using Monte Carlo Simulation

Load the data set.

```
load carbig
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Use a Monte Carlo simulation to obtain an exact *P*-value.

```
[h,p,jbstat,critval] = jbtest(MPG,[],0.0001)
```

```
h =
```

```
    1
```

```
p =
```

```
    0.0022
```

```
jbstat =
```

```
    18.2275
```

```
critval =
```

```
    5.8461
```

The returned value of `h = 1` indicates that `jbtest` rejects the null hypothesis at the default 5% significance level. Additionally, the test statistic, `jbstat`, is larger than the critical value, `critval`, which indicates rejection of the null hypothesis.

Input Arguments

x — Sample data

vector

Sample data for the hypothesis test, specified as a vector. `jbtest` treats NaN values in `x` as missing values and ignores them.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as a scalar value in the range (0,1). If `alpha` is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, `jbstest` looks up the critical value for the test in a table of precomputed values. To conduct the test at a significance level outside of these specifications, use `mctol`.

Example: 0.01

Data Types: `single` | `double`

mctol — Maximum Monte Carlo standard error

nonnegative scalar value

Maximum Monte Carlo standard error for the p -value, `p`, specified as a nonnegative scalar value. If you specify a value for `mctol`, `jbstest` computes a Monte Carlo approximation for `p` directly, rather than interpolating into a table of precomputed values. `jbstest` chooses the number of Monte Carlo replications large enough to make the Monte Carlo standard error for `p` less than `mctol`.

If you specify a value for `mctol`, you must also specify a value for `alpha`. You can specify `alpha` as `[]` to use the default value of 0.05.

Example: 0.0001

Data Types: `single` | `double`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If `h` = 1, this indicates the rejection of the null hypothesis at the `alpha` significance level.
- If `h` = 0, this indicates a failure to reject the null hypothesis at the `alpha` significance level.

p — p -value

scalar value in the range (0,1)

p -value of the test, returned as a scalar value in the range (0,1). `p` is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of `p` cast doubt on the validity of the null hypothesis.

`jbtest` warns when `p` is not found within the tabulated range of [0.001,0.50], and returns either the smallest or largest tabulated value. In this case, you can use `mctol` to compute a more accurate p -value.

jbstat — Test statistic

nonnegative scalar value

Test statistic for the Jarque-Bera test, returned as a nonnegative scalar value.

critval — Critical value

nonnegative scalar value

Critical value for the Jarque-Bera test at the `alpha` significance level, returned as a nonnegative scalar value. If `alpha` is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, `jbtest` looks up the critical value for the test in a table of precomputed values. If you use `mctol`, `jbtest` determines the critical value of the test using a Monte Carlo simulation. The null hypothesis is rejected when `jbstat` > `critval`.

Definitions

Jarque-Bera Test

The Jarque-Bera test is a two-sided goodness-of-fit test suitable when a fully specified null distribution is unknown and its parameters must be estimated.

The test is specifically designed for alternatives in the Pearson system of distributions. The test statistic is

$$JB = \frac{n}{6} \left(s^2 + \frac{(k-3)^2}{4} \right),$$

where n is the sample size, s is the sample skewness, and k is the sample kurtosis. For large sample sizes, the test statistic has a chi-square distribution with two degrees of freedom.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the p -value.

The Monte Carlo standard error is calculated as

$$SE = \sqrt{\frac{(\hat{p})(1 - \hat{p})}{\text{mcreps}}},$$

where \hat{p} is the estimated p -value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed. `jbttest` chooses the number of Monte Carlo replications, `mcreps`, large enough to make the Monte Carlo standard error for \hat{p} less than the value specified for `mctol`.

Algorithm

Jarque-Bera tests often use the chi-square distribution to estimate critical values for large samples, deferring to the Lilliefors test (see `lillietest`) for small samples. `jbttest`, by contrast, uses a table of critical values computed using Monte Carlo simulation for sample sizes less than 2000 and significance levels from 0.001 to 0.50. Critical values for a test are computed by interpolating into the table, using the analytic chi-square approximation only when extrapolating for larger sample sizes.

Topics

“Generating Data Using the Pearson System” on page 7-29

Introduced before R2006a

johnsrnd

Johnson system random numbers

Syntax

```
r = johnsrnd(quantiles,m,n)
r = johnsrnd(quantiles)
[r,type] = johnsrnd(...)
[r,type,coefs] = johnsrnd(...)
```

Description

`r = johnsrnd(quantiles,m,n)` returns an m -by- n matrix of random numbers drawn from the distribution in the Johnson system that satisfies the quantile specification given by `quantiles`. `quantiles` is a four-element vector of quantiles for the desired distribution that correspond to the standard normal quantiles $[-1.5 -0.5 0.5 1.5]$. In other words, you specify a distribution from which to draw random values by designating quantiles that correspond to the cumulative probabilities $[0.067 0.309 0.691 0.933]$. `quantiles` may also be a 2-by-4 matrix whose first row contains four standard normal quantiles, and whose second row contains the corresponding quantiles of the desired distribution. The standard normal quantiles must be spaced evenly.

Note: Because `r` is a random sample, its sample quantiles typically differ somewhat from the specified distribution quantiles.

`r = johnsrnd(quantiles)` returns a scalar value.

`r = johnsrnd(quantiles,m,n,...)` or `r = johnsrnd(quantiles,[m,n,...])` returns an m -by- n -by-... array.

`[r,type] = johnsrnd(...)` returns the type of the specified distribution within the Johnson system. `type` is 'SN', 'SL', 'SB', or 'SU'. Set `m` and `n` to zero to identify the distribution type without generating any random values.

The four distribution types in the Johnson system correspond to the following transformations of a normal random variate:

- 'SN' — Identity transformation (normal distribution)
- 'SL' — Exponential transformation (lognormal distribution)
- 'SB' — Logistic transformation (bounded)
- 'SU' — Hyperbolic sine transformation (unbounded)

`[r,type,coefs] = johnsrnd(...)` returns coefficients `coefs` of the transformation that defines the distribution. `coefs` is `[gamma, eta, epsilon, lambda]`. If `z` is a standard normal random variable and `h` is one of the transformations defined above, $r = \lambda * h((z - \text{gamma}) / \text{eta}) + \text{epsilon}$ is a random variate from the distribution `type` corresponding to `h`.

Examples

Generate Random Samples Using the Johnson System

This example shows several different approaches to using the Johnson system of flexible distribution families to generate random numbers and fit a distribution to sample data.

Generate random values with longer tails than a standard normal.

```
rng default; % For reproducibility
r = johnsrnd([-1.7 -.5 .5 1.7],1000,1);
figure;
qqplot(r);
```

Generate random values skewed to the right.

```
r = johnsrnd([-1.3 -.5 .5 1.7],1000,1);  
figure;  
qqplot(r);
```

Generate random values that match some sample data well in the right-hand tail.

```
load carbig;
qnorm = [.5 1 1.5 2];
q = quantile(Acceleration, normcdf(qnorm));
r = johnsrnd([qnorm;q],1000,1);
[q;quantile(r,normcdf(qnorm))]
```

ans =

```
16.7000    18.2086    19.5376    21.7263
16.6986    18.2220    19.9078    22.0918
```

Determine the distribution type and the coefficients.

```
[r,type,coefs] = johnsrnd([qnorm;q],0)

Introduced in R2006a

join

Class: dataset

Merge observations

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = join(A,B)
C = join(A,B,keys)
C = join(A,B,param1,val1,param2,val2,...)
[C,IB] = join(...)
C = join(A,B,'Type',TYPE,...)
C = join(A,B,'Type',TYPE,'MergeKeys',true,...)
[C,IA,IB] = join(A,B,'Type',TYPE,...)
```

Description

`C = join(A,B)` creates a dataset array `C` by merging observations from the two dataset arrays `A` and `B`. `join` performs the merge by first finding *key variables*, that is, pairs of dataset variables, one in `A` and one in `B`, that share the same name. Each observation in `B` must contain a unique combination of values in the key variables, and must contain all combinations of values that are present in the keys from `A`. `join` then uses these key variables to define a many-to-one correspondence between observations in `A` and those in `B`. `join` uses this correspondence to replicate the observations in `B` and combine them with the observations in `A` to create `C`.

`C = join(A,B,keys)` performs the merge using the variables specified by `keys` as the key variables in both `A` and `B`. `keys` is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

C contains one observation for each observation in **A**. Variables in **C** include all of the variables from **A**, as well as one variable corresponding to each variable in **B** (except for the keys from **B**). If **A** and **B** contain variables with identical names, `join` adds the suffix `'_left'` and `'_right'` to the corresponding variables in **C**.

`C = join(A,B,param1,va11,param2,va12,...)` specifies optional parameter name/value pairs to control how the dataset variables in **A** and **B** are used in the merge. Parameters are:

- `'Keys'` — Specifies the variables to use as keys in both **A** and **B**.
- `'LeftKeys'` — Specifies the variables to use as keys in **A**.
- `'RightKeys'` — Specifies the variables to use as keys in **B**.

You may provide either the `'Keys'` parameter, or both the `'LeftKeys'` and `'RightKeys'` parameters. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing variable names, or a logical vector. `'LeftKeys'` or `'RightKeys'` must both specify the same number of key variables, and `join` pairs the left and right keys in the order specified.

- `'LeftVars'` — Specifies which variables from **A** to include in **C**. By default, `join` includes all variables from **A**.
- `'RightVars'` — Specifies which variables from **B** to include in **C**. By default, `join` includes all variables from **B** except the key variables.

You can use `'LeftVars'` or `'RightVars'` to include or exclude key variables as well as data variables. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

`[C,IB] = join(...)` returns an index vector **IB**, where `join` constructs **C** by horizontally concatenating `A(:,LeftVars)` and `B(IB,RightVars)`. `join` can also perform more complicated inner and outer join operations that allow a many-to-many correspondence between **A** and **B**, and allow unmatched observations in either **A** or **B**.

`C = join(A,B,'Type',TYPE,...)` performs the join operation specified by **TYPE**. **TYPE** is one of `'inner'`, `'leftouter'`, `'rightouter'`, `'fullouter'`, or `'outer'` (which is a synonym for `'fullouter'`). For an inner join, **C** only contains observations corresponding to a combination of key values that occurred in both **A** and **B**. For a left (or right) outer join, **C** also contains observations corresponding to keys in **A** (or **B**) that did not match any in **B** (or **A**). Variables in **C** taken from **A** (or **B**) contain null values in those observations. A full outer join is equivalent to a left and right outer join. **C** contains

variables corresponding to the key variables from both A and B, and `join` sorts the observations in C by the key values.

For inner and outer joins, C contains variables corresponding to the key variables from both A and B by default, as well as all the remaining variables. `join` sorts the observations in the result C by the key values.

`C = join(A,B, 'Type', TYPE, 'MergeKeys', true, ...)` includes a single variable in C for each key variable pair from A and B, rather than including two separate variables. For outer joins, `join` creates the single variable by merging the key values from A and B, taking values from A where a corresponding observation exists in A, and from B otherwise. Setting the 'MergeKeys' parameter to `true` overrides inclusion or exclusion of any key variables specified via the 'LeftVars' or 'RightVars' parameter. Setting the 'MergeKeys' parameter to `false` is equivalent to not passing in the 'MergeKeys' parameter.

`[C, IA, IB] = join(A,B, 'Type', TYPE, ...)` returns index vectors IA and IB indicating the correspondence between observations in C and those in A and B. For an inner join, `join` constructs C by horizontally concatenating `A(IA, LeftVars)` and `B(IB, RightVars)`. For an outer join, IA or IB may also contain zeros, indicating the observations in C that do not correspond to observations in A or B, respectively.

Examples

Create a dataset array from Fisher's iris data:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'}, num2str((1:NumObs)', '%-d'));
iris = dataset({nominal(species), 'species'}, ...
               {meas, 'SL', 'SW', 'PL', 'PW'}, ...
               'ObsNames', NameObs);
```

Create a separate dataset array with the diploid chromosome counts for each species of iris:

```
snames = nominal({'setosa'; 'versicolor'; 'virginica'});
CC = dataset({snames, 'species'}, {[38;108;70], 'cc'})
CC =
    species      cc
    setosa       38
    versicolor   108
```

```
virginica      70
```

Broadcast the data in `CC` to the rows of `iris` using the key variable `species` in each dataset:

```
iris2 = join(iris,CC);
iris2([1 2 51 52 101 102],:)
ans =
```

	species	SL	SW	PL	PW	cc
Obs1	setosa	5.1	3.5	1.4	0.2	38
Obs2	setosa	4.9	3	1.4	0.2	38
Obs51	versicolor	7	3.2	4.7	1.4	108
Obs52	versicolor	6.4	3.2	4.5	1.5	108
Obs101	virginica	6.3	3.3	6	2.5	70
Obs102	virginica	5.8	2.7	5.1	1.9	70

Create two datasets and join them using the `'MergeKeys'` flag:

```
% Create two data sets that both contain the key variable
% 'Key1'. The two arrays contain observations with common
% values of Key1, but each array also contains observations
% with values of Key1 not present in the other.
a = dataset({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
    'VarNames',{'Key1' 'Var1'})
b = dataset({'a' 'b' 'd' 'e'},[4 5 6 7]',...
    'VarNames',{'Key1' 'Var2'})

% Combine a and b with an outer join, which matches up
% observations with common key values, but also retains
% observations whose key values don't have a match.
% Keep the key values as separate variables in the result.
couter = join(a,b,'key','Key1','Type','outer')

% Join a and b, merging the key values as a single variable
% in the result.
coutermerge = join(a,b,'key','Key1','Type','outer',...
    'MergeKeys',true)

% Join a and b, retaining only observations whose key
% values match.
cinner = join(a,b,'key','Key1','Type','inner',...
    'MergeKeys',true)

a =
```

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

b =

Key1	Var2
'a'	4
'b'	5
'd'	6
'e'	7

couter =

Key1_left	Var1	Key1_right	Var2
'a'	1	'a'	4
'b'	2	'b'	5
'c'	3	''	NaN
''	NaN	'd'	6
'e'	11	'e'	7
'h'	17	''	NaN

coutermerge =

Key1	Var1	Var2
'a'	1	4
'b'	2	5
'c'	3	NaN
'd'	NaN	6
'e'	11	7
'h'	17	NaN

cinner =

Key1	Var1	Var2
'a'	1	4
'b'	2	5

'e' 11 7

KDTreeSearcher

Grow *Kd*-tree

Syntax

```
Mdl = KDTreeSearcher(X)
Mdl = KDTreeSearcher(X,Name,Value)
```

Description

`Mdl = KDTreeSearcher(X)` grows a default *Kd*-tree (`Mdl`) using the n -by- K numeric matrix of training data (`X`). `Mdl` is a `KDTreeSearcher` model object that stores the results of the grown *Kd*-tree. You can use `Mdl` to search the training data (`X`) for the nearest neighbors to the query data.

`Mdl = KDTreeSearcher(X,Name,Value)` grows a *Kd*-tree (`Mdl`) with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify a distance metric or the maximum number of observations in each leaf node (i.e., the bucket size).

Examples

Grow a Default *K d*-Tree

Load Fisher's iris data set.

```
load fisheriris
X = meas;
[n,k] = size(X)
```

```
n =
```

```
150
```

```
k =
    4
```

X has 150 observations and 4 predictors.

Grow a 4-dimensional K d-tree using the entire data set as training data.

```
Mdl = KDTreeSearcher(X)
```

```
Mdl =
```

```
KDTreeSearcher with properties:
```

```
    BucketSize: 50
    Distance: 'euclidean'
    DistParameter: []
    X: [150x4 double]
```

Mdl is a KDTreeSearcher model object, and its properties appear in the Command Window. It contains information about the grown 4-dimensional K d-tree, such as the distance metric. You can alter property values using dot notation

To find the nearest neighbors in X to a batch of query data, pass Mdl and the query data to knnsearch or rangesearch.

Specify the Minkowski Distance for Nearest Neighbor Search

Load Fisher's iris data. Focus on the petal dimensions.

```
load fisheriris
X = meas(:, [3 4]); % Predictors
```

Grow a two-dimensional K d-tree using createns and the training data. Specify the Minkowski distance metric.

```
Mdl = createns(X, 'NSMethod', 'kdtree', 'Distance', 'Minkowski')
```

```
Mdl =
```

KDTreeSearcher with properties:

```
    BucketSize: 50
    Distance: 'minkowski'
    DistParameter: 2
    X: [150×2 double]
```

Mdl is a KDTreeSearcher model object. Access properties of Mdl using dot notation. For example, use Mdl.DistParameter to access the Minkowski distance exponent.

```
Mdl.DistParameter
```

```
ans =
```

```
    2
```

You can pass query data and Mdl to:

- knnsearch to find indices and distances of nearest neighbors.
- rangearch to find indices of all nearest neighbors within a distance that you specify.

Search for Nearest Neighbors of Query Data Using the Minkowski Distance

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
tIdx = ~ismember(1:n,qIdx); % Indices of training data
Q = meas(qIdx,:);
X = meas(tIdx,:);
```

Grow a four-dimensional K d-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors later.

```
Mdl = createns(X, 'NSMethod', 'kdtree', 'Distance', 'minkowski')
```

```
Mdl =
    KDTreeSearcher with properties:
        BucketSize: 50
        Distance: 'minkowski'
        DistParameter: 2
        X: [145x4 double]
```

Mdl is a KDTreeSearcher model object. By default, the Minkowski distance exponent is 2.

Find the indices of the training data (X) that are the two nearest neighbors of each point in the query data (Q).

```
IdxNN = knnsearch(Mdl,Q,'K',2)
```

```
IdxNN =
     17     4
      6     2
      1    12
     89    66
    124   100
```

Each row of NN corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors. For example, using the Minkowski distance, the second nearest neighbor of Q(3, :) is X(12, :).

Input Arguments

X — Training data

numeric matrix

Training data that grows the *Kd*-tree, specified as a numeric matrix. X has *n* rows, each corresponding to an observation (i.e., an instance or example), and *K* columns, each corresponding to a predictor or feature.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Distance', 'minkowski', 'P', 3, 'BucketSize', 10` specifies to use the Minkowski distance when searching for nearest neighbors, to use 3 for the Minkowski distance metric exponent, and to use 10 for the bucket size.

'Distance' — Distance metric

`'euclidean'` (default) | `'chebychev'` | `'cityblock'` | `'minkowski'`

Distance metric used to find nearest neighbors of query points, specified as the comma-separated pair consisting of `'Distance'` and one of these values.

Value	Description
<code>'chebychev'</code>	Chebychev distance (maximum coordinate difference)
<code>'cityblock'</code>	City block distance
<code>'euclidean'</code>	Euclidean distance
<code>'minkowski'</code>	Minkowski distance

For more details, see “Distance Metrics” on page 18-10.

The software does not use the distance metric for training the *Kd*-tree, so you can alter it after training using dot notation.

Example: `'Distance', 'minkowski'`

Data Types: char

'P' — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar. If you specify `P` and do not specify `'Distance', 'minkowski'`, then the software throws an error.

Example: `'P', 3`

Data Types: `double` | `single`

'BucketSize' — Maximum number of data points in each leaf node

50 (default) | positive integer

Maximum number of data points in each leaf node of the *Kd*-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer.

Example: `'BucketSize',10`

Data Types: `double` | `single`

Output Arguments

Mdl — Grown *Kd*-tree

KDTreeSearcher model object

Grown *Kd*-tree, returned as a KDTreeSearcher model object. To search the training data for the nearest neighbors of the query data, pass the query data and Mdl to `knnsearch` or `rangearch`.

Introduced in R2010a

KDTreeSearcher

Nearest neighbor search using *Kd*-tree

Description

`KDTreeSearcher` model objects store results of a nearest neighbors search using the *Kd*-tree algorithm. Results that you can store include the training data, the distance metric and its parameters, and the maximal number of data points in each leaf node (i.e., the bucket size). The *Kd*-tree algorithm partitions an n -by- K data set by recursively splitting n points in K -dimensional space into a binary tree. To find the nearest neighbors of a query observation, `KDTreeSearcher` restricts the training data space to the training observations in the leaf node that the query observation belongs to.

Once you create or train a `KDTreeSearcher` model object, you can search the stored tree to find all neighboring points to the query data by performing a nearest neighbors search using `knnsearch` or radius search using `rangesearch`. The *Kd*-tree algorithm is particularly useful when:

- K is relatively small (i.e., $K < 10$).
- The training and query sets are not sparse.
- The training and query sets have many observations.

Create Object

Train a `KDTreeSearcher` model object using `KDTreeSearcher` or `createns`.

Properties

Distance — Distance metric

`'chebychev' | 'cityblock' | 'euclidean' | 'minkowski'`

Distance metric used to find nearest neighbors of query points, specified as one of these values.

Value	Description
'chebychev'	Chebychev distance (maximum coordinate difference)
'cityblock'	City block distance
'euclidean'	Euclidean distance
'minkowski'	Minkowski distance

For more details, see “Distance Metrics” on page 18-10.

The software does not use the distance metric for training the *Kd*-tree, so you can alter it after training using dot notation.

Data Types: char

DistParameter — Distance metric parameter values

[] | positive scalar

Distance metric parameter values, specified as empty ([]) or as a positive scalar.

If `Distance` is 'minkowski', then:

- `DistParameter` is the exponent in the Minkowski distance formula.
- You can alter `DistParameter` of a trained `KDTreeSearcher` model.

Otherwise, `DistParameter` is [], indicating that the specified distance metric formula has no parameters.

Data Types: single | double

X — Training data

numeric matrix

This property is read-only.

Training data that grows the *Kd*-tree, specified as a numeric matrix. *X* has *n* rows, each corresponding to an observation (i.e., an instance or example), and *K* columns, each corresponding to a predictor or feature.

Data Types: single | double

Object Functions

knnsearch

k-nearest neighbors search using Kd-tree or exhaustive search

rangesearch

Find all neighbors within specified distance using exhaustive search or Kd-tree

Examples

Grow a Default K d-Tree

Load Fisher's iris data set.

```
load fisheriris
X = meas;
[n,k] = size(X)
```

```
n =
```

```
    150
```

```
k =
```

```
     4
```

X has 150 observations and 4 predictors.

Grow a 4-dimensional K d-tree using the entire data set as training data.

```
Mdl = KDTreeSearcher(X)
```

```
Mdl =
```

```
    KDTreeSearcher with properties:
```

```
    BucketSize: 50
    Distance: 'euclidean'
    DistParameter: []
    X: [150×4 double]
```

Mdl is a `KDTreesearcher` model object, and its properties appear in the Command Window. It contains information about the grown 4-dimensional K d-tree, such as the distance metric. You can alter property values using dot notation

To find the nearest neighbors in X to a batch of query data, pass Mdl and the query data to `knnsearch` or `rangesearch`.

Alter Properties of KDTreesearcher Model

Load Fisher's iris data set.

```
load fisheriris
X = meas;
```

Grow a default four-dimensional K d-tree using the entire data set as training data.

```
Mdl = KDTreesearcher(X)
```

```
Mdl =
```

```
    KDTreesearcher with properties:
```

```
        BucketSize: 50
           Distance: 'euclidean'
    DistParameter: []
                X: [150x4 double]
```

Specify that the neighbor searcher use the Minkowski metric to compute the distances between the training and query data.

```
Mdl.Distance = 'minkowski'
```

```
Mdl =
```

```
    KDTreesearcher with properties:
```

```
        BucketSize: 50
           Distance: 'minkowski'
    DistParameter: 2
                X: [150x4 double]
```

Pass `Mdl` and the query data to either `knnsearch` or `rangesearch` to find the nearest neighbors to the points in the query data using the Minkowski distance.

Search for Nearest Neighbors of Query Data Using the Minkowski Distance

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
tIdx = ~ismember(1:n,qIdx); % Indices of training data
Q = meas(qIdx,:);
X = meas(tIdx,:);
```

Grow a four-dimensional K d-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors later.

```
Mdl = createns(X, 'NSMethod', 'kdtree', 'Distance', 'minkowski')
```

```
Mdl =
```

```
    KDTreeSearcher with properties:
```

```
        BucketSize: 50
           Distance: 'minkowski'
    DistParameter: 2
                X: [145×4 double]
```

`Mdl` is a `KDTreeSearcher` model object. By default, the Minkowski distance exponent is 2.

Find the indices of the training data (`X`) that are the two nearest neighbors of each point in the query data (`Q`).

```
IdxNN = knnsearch(Mdl,Q, 'K', 2)
```

IdxNN =

17	4
6	2
1	12
89	66
124	100

Each row of NN corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors. For example, using the Minkowski distance, the second nearest neighbor of $Q(3, :)$ is $X(12, :)$.

Kernel property

Class: ProbDistKernel

Read-only name of kernel smoothing function for ProbDistKernel object

Description

`Kernel` is a read-only property of the ProbDistKernel class. `Kernel` is a character vector specifying the name of the kernel smoothing function used to create a ProbDistKernel object.

Values

'normal'
'box'
'triangle'
'epanechnikov'

Use this information to view and compare the kernel smoothing function used to create distributions.

See Also

`ksdensity`

prob.KernelDistribution class

Package: prob

Superclasses: prob.TruncatableDistribution

Kernel probability distribution object

Description

prob.KernelDistribution is an object consisting of parameters, a model description, and sample data for a nonparametric kernel-smoothing distribution. Create a prob.KernelDistribution object using `fitdist` or `distributionFitter`.

Construction

`pd = fitdist(x, 'Kernel')` creates a probability distribution object by fitting a kernel-smoothing distribution to the data in `x`.

`pd = fitdist(x, 'Kernel', Name, Value)` creates a probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can change the kernel function or specify the kernel bandwidth.

Input Arguments

x — Input data

column vector

Input data to fit with a kernel-smoothing distribution, specified as a column vector of scalar values. `fitdist` ignores NaN values in `x`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Kernel' — Kernel smoother type`'normal' (default) | 'box' | 'triangle' | 'epanechnikov'`

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and one of the following kernel smoothing function types:

- 'normal'
- 'box'
- 'triangle'
- 'epanechnikov'

'Support' — Kernel density support`'unbounded' (default) | 'positive' | two-element vector`

Kernel density support, specified as the comma-separated pair consisting of 'Support' and a character vector or two-element vector. The character vector must be one of the following.

<code>'unbounded'</code>	Density can extend over the whole real line.
<code>'positive'</code>	Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

Data Types: `single` | `double`

'Width' — Bandwidth of kernel smoothing window

scalar value

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of 'Width' and a scalar value. The default value used by `fitdist` is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes.

Data Types: `single` | `double`

Properties

Kernel — Kernel smoother type`'normal' | 'box' | 'triangle' | 'epanechnikov'`

Kernel function type, stored as a valid kernel function type name.

BandWidth — Bandwidth of kernel smoothing window

positive scalar value

Bandwidth of the kernel smoothing window, stored as a positive scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

character vector

Probability distribution name, stored as a character vector. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

Methods

<code>mean</code>	Mean of probability distribution object
<code>negloglik</code>	Negative loglikelihood
<code>std</code>	Standard deviation of probability distribution object
<code>var</code>	Variance of probability distribution object

Inherited Methods

<code>cdf</code>	Cumulative distribution function of probability distribution object
<code>icdf</code>	Inverse cumulative distribution function of probability distribution object
<code>iqr</code>	Interquartile range of probability distribution object
<code>median</code>	Median of probability distribution object
<code>pdf</code>	Probability density function of probability distribution object
<code>random</code>	Generate random numbers from probability distribution object
<code>truncate</code>	Truncate probability distribution object

Examples

Fit a Kernel Distribution Object to Data

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital
histogram(hospital.Weight)
```

The histogram shows that the data has two modes, one for female patients and one for male patients.

Create a probability distribution object by fitting a kernel distribution to the patient weight data.

```
pd_kernel = fitdist(hospital.Weight, 'Kernel')
```

```
pd_kernel =
```

```
KernelDistribution
```

```
Kernel = normal
```

```
Bandwidth = 14.3792
Support = unbounded
```

For comparison, create another probability distribution object by fitting a normal distribution to the patient weight data.

```
pd_normal = fitdist(hospital.Weight, 'Normal')
```

```
pd_normal =
NormalDistribution
Normal distribution
    mu =      154    [148.728, 159.272]
    sigma = 26.5714 [23.3299, 30.8674]
```

Define the x values and compute the pdf of each distribution.

```
x = 50:1:250;
pdf_kernel = pdf(pd_kernel,x);
pdf_normal = pdf(pd_normal,x);
```

Plot the pdf of each distribution.

```
plot(x,pdf_kernel, 'Color', 'b', 'LineWidth',2);
hold on;
plot(x,pdf_normal, 'Color', 'r', 'LineStyle', ':', 'LineWidth',2);
legend('Kernel Distribution', 'Normal Distribution', 'Location', 'SouthEast');
hold off;
```

Fitting a kernel distribution instead of a unimodal distribution such as the normal reveals the separate modes for the female and male patients.

- “Fit Kernel Distribution Object to Data” on page 5-50

Definitions

Kernel Distribution

The kernel distribution is a nonparametric estimation of the probability density function (pdf) of a random variable.

The kernel distribution uses the following options.

Option	Description	Possible Values
Kernel	Kernel function type	normal, box, triangle, epanechnikov
BandWidth	Kernel smoothing parameter	BandWidth > 0

The kernel density estimator is

$$\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x-x_i}{h}\right) ; \quad -\infty < x < \infty,$$

where n is the sample size, $K(\cdot)$ is the kernel function, and h is the bandwidth.

Class Attributes (MATLAB)

Property Attributes (MATLAB)

kfoldEdge

Class: ClassificationPartitionedECOC

Classification edge for observations not used for training

Syntax

```
edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl,Name,Value)
```

Description

`edge = kfoldEdge(CVMdl)` returns the classification edge obtained by the cross-validated ECOC model (ClassificationPartitionedECOC) `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for in-fold observations using an ECOC model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

`edge = kfoldEdge(CVMdl,Name,Value)` returns the classification edge with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the number of folds, decoding scheme, or verbosity level.

Input Arguments

CVMdl — Cross-validated ECOC model

ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a ClassificationPartitionedECOC model. You can create a ClassificationPartitionedECOC model by:

- Passing a trained ECOC model (ClassificationECOC) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge'
| 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` should have this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 29-4911.

By default, if all binary learners are:

- SVMs or linear classification models of SVM learners, then `BinaryLoss` is 'hinge'
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is 'exponential'
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is 'binodeviance'
- Linear classification models of logistic regression learners, or you specify to predict class posterior probabilities (i.e., set 'FitPosterior', 1 in `fitcecoc`), then `BinaryLoss` is 'quadratic'

Otherwise, the default `BinaryLoss` is 'hamming'. To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | function_handle

'Decoding' — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses on page 29-4919, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'.

Example: 'Decoding', 'lossbased'

Data Types: char

'Folds' — Fold indices for prediction

1:Mdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `Mdl.KFold`.

The software only uses the folds specified in `Folds` for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

'Mode' — Edge aggregation level

'average' (default) | 'individual'

Edge meaning, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

This table describes the values.

Value	Description
'average'	edge is the scalar average over all folds.
'individual'	edge is a vector of length k containing one edge per fold. k is the number of folds.

Example: `'Mode','individual'`

Data Types: `char`

'Options' — Estimation options[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

edge — Classification edge

numeric scalar | numeric row vector

Classification edge, returned as a numeric scalar or numeric row vector.

If `Mode` is `'average'`, then `edge` is the average classification edge among all binary learners. Otherwise, `edge` is a 1-by-L numeric row vector containing the classification edge for each, respective binary learner, where L is the number of binary learners (`size(CVMdl.CodingMatrix,2)`).

Data Types: `single` | `double`

Examples

Estimate *k*-Fold Cross-Validation Edge of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
```

```
CVMD1 = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMD1 is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold edges.

```
edge = kfoldEdge(CVMD1)
```

```
edge =
```

```
0.4825
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode', 'individual' in `kfoldEdge`.

Display Individual Edges for Each Cross-Validation Fold

The classification edge is a relative measure of classifier quality. You can determine ill-performing folds by displaying the edges for each fold.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to use 8-fold cross validation. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMD1 = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the classification edge for each fold.

```
edges = kfoldEdge(CVMD1,'Mode','individual')
```

```
edges =
```

```

0.4790
0.4872
0.4260
0.5301
0.5064
0.4575
0.4860
0.4687

```

The edges have similar magnitudes across folds. Ill-performing folds have low edges relative to the other folds.

You can return the classification edge for the entire model by specifying the well-performing folds using the 'Folds' name-value pair argument.

Select ECOC Model Features by Comparing Cross-Validation Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare cross-validation edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set.

```

load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility

```

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the petal dimensions.

```

fullX = X;
partX = X(:,3:4);

```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify to cross validate. It is good practice to define the class order. Specify to standardize the predictors using an SVM template.

```

t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...

```

```
'ClassNames',classOrder);  
PCVMd1 = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...  
  'ClassNames',classOrder);
```

CVMD1 and PCVMd1 are ClassificationPartitionedECOC models. By default, the software implements 10-fold cross validation.

Estimate the test-sample edge for each classifier.

```
fullEdge = kfoldEdge(CVMd1)  
partEdge = kfoldEdge(PCVMd1)
```

```
fullEdge =  
    0.4825
```

```
partEdge =  
    0.4951
```

PCVMd1 achieves an edge that is similar to the more complex model CVMd1.

- “Quick Start Parallel Computing for Statistics and Machine Learning Toolbox” on page 27-2

Definitions

Classification Edge

The *classification edge* is the weighted mean of the *classification margins*.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the true class and maximal negative loss among the false classes. If the margins

are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the `LossFun` name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

kfoldEdge

Class: ClassificationPartitionedEnsemble

Classification edge for observations not used for training

Syntax

```
E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)
```

Description

`E = kfoldEdge(obj)` returns classification edge (average classification margin) obtained by cross-validated classification ensemble `obj`. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

`E = kfoldEdge(obj,Name,Value)` calculates edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'folds'

Indices of folds ranging from 1 to `ens.KFold`. Use only these folds for predictions.

Default: `1:ens.KFold`

'mode'

Character vector representing the meaning of the output `edge`:

- 'average' — `edge` is a scalar value, the average over all folds.
- 'individual' — `edge` is a vector of length `ens.KFold` with one element per fold.
- 'cumulative' — `edge` is a vector of length `min(ens.NTrainedPerFold)` in which element `J` is obtained by averaging values across all folds for weak learners `1:J` in each fold.

Default: 'average'

Output Arguments

E

The average classification margin. `E` is a scalar or vector, depending on the setting of the `mode` name-value pair.

Examples

Compute the k-fold `edge` for an ensemble trained on the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
cvens = crossval(ens);
E = kfoldEdge(cvens)
```

```
E =
    3.2078
```

Definitions

Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `obj.Prior`.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `obj.X`.

Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

Topics

kfoldEdge

Class: ClassificationPartitionedLinear

Classification edge for observations not used for training

Syntax

```
e = kfoldEdge(CVMd1)
e = kfoldEdge(CVMd1, Name, Value)
```

Description

`e = kfoldEdge(CVMd1)` returns the cross-validated classification edges obtained by the cross-validated, binary, linear classification model `CVMd1`. That is, for every fold, `kfoldEdge` estimates the classification edge for observations that it holds out when it trains using all other observations.

`e` contains a classification edge for each regularization strength in the linear classification models that comprise `CVMd1`.

`e = kfoldEdge(CVMd1, Name, Value)` uses additional options specified by one or more `Name, Value` pair arguments. For example, indicate which folds to use for the edge calculation.

Input Arguments

CVMd1 — Cross-validated, binary, linear classification model

ClassificationPartitionedLinear model object

Cross-validated, binary, linear classification model, specified as a ClassificationPartitionedLinear model object. You can create a ClassificationPartitionedLinear model using `fitlinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, ClassificationPartitionedLinear.kfoldEdge applies the same data used to cross-validate the linear classification model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Folds' — Fold indices to use for classification-score prediction

1:CVMD1.KFold (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through CVMD1.KFold.

Example: 'Folds',[1 4 10]

Data Types: single | double

'Mode' — Edge aggregation level

'average' (default) | 'individual'

Edge aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

Value	Description
'average'	Returns classification edges averaged over all folds
'individual'	Returns classification edges for each fold

Example: 'Mode','individual'

Data Types: char

Output Arguments

e — Cross-validated classification edges

numeric scalar | numeric vector | numeric matrix

Cross-validated classification edges, returned as a numeric scalar, vector, or matrix.

Let L be the number of regularization strengths in the cross-validated models (that is, L is `numel(CVMdl.Trained{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is `'average'`, then \mathbf{e} is a 1-by- L vector. $\mathbf{e}(j)$ is the average classification edge over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, \mathbf{e} is an F -by- L matrix. $\mathbf{e}(i, j)$ is the classification edge for fold i of the cross-validated model that uses regularization strength j .

To estimate \mathbf{e} , `kfoldEdge` uses the data that created `CVMdl` (see X and Y).

Examples

Estimate k -Fold Cross-Validation Edge

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility  
CVMdl = fitlinear(X, Ystats, 'CrossVal', 'on');
```

`CVMdl` is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the average of the out-of-fold edges.

```
e = kfoldEdge(CVMdl)
```

```
e =  
8.1243
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode', 'individual' in kfoldEdge.

Feature Selection Using *k*-fold Edges

One way to perform feature selection is to compare *k*-fold edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set. Preprocess the data as in “Estimate *k*-Fold Cross-Validation Edge”.

```
load nlpdata  
Ystats = Y == 'stats';  
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility  
p = size(X,1); % Number of predictors  
halfPredIdx = randsample(p,ceil(0.5*p));  
fullX = X;  
partX = X(halfPredIdx,:);
```

Cross-validate two binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Optimize the objective function using SpaRSA, and indicate that observations correspond to columns.

```
CVMdl = fitlinear(fullX,Ystats,'CrossVal','on','Solver','sparsa',...  
    'ObservationsIn','columns');  
PCVMdl = fitlinear(partX,Ystats,'CrossVal','on','Solver','sparsa',...  
    'ObservationsIn','columns');
```

CVMdl and PCVMdl are ClassificationPartitionedLinear models.

Estimate the k -fold edge for each classifier.

```
fullEdge = kfoldEdge(CVMdl)
partEdge = kfoldEdge(PCVMdl)
```

```
fullEdge =
```

```
    16.5629
```

```
partEdge =
```

```
    13.9030
```

Based on the k -fold edges, the classifier that uses all of the predictors is the better model.

Find Good Lasso Penalty Using k -fold Edge

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare k -fold edges.

Load the NLP data set. Preprocess the data as in “Estimate k -Fold Cross-Validation Edge”.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8,1,11);
```

Cross-validate a binary, linear classification model using 5-fold cross-validation and that uses each of the regularization strengths. Optimize the objective function using SpARSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility
CVMdl = fitlinear(X,Ystats,'ObservationsIn','columns','KFold',5,...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8)
```

```

CVMd1 =

classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 5
  Partition: [1×1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'

```

`CVMd1` is a `ClassificationPartitionedLinear` model. Because `fitclinear` implements 5-fold cross-validation, `CVMd1` contains 5 `ClassificationLinear` models that the software trains on each fold.

Estimate the edges for each fold and regularization strength.

```
eFolds = kfoldEdge(CVMd1, 'Mode', 'individual')
```

```
eFolds =
```

```
Columns 1 through 7
```

0.9958	0.9958	0.9958	0.9958	0.9958	0.9923	0.9770
0.9990	0.9990	0.9990	0.9990	0.9990	0.9937	0.9780
0.9992	0.9992	0.9992	0.9992	0.9992	0.9943	0.9781
0.9974	0.9974	0.9974	0.9974	0.9974	0.9931	0.9772
0.9977	0.9977	0.9977	0.9977	0.9977	0.9942	0.9781

```
Columns 8 through 11
```

0.9167	0.8444	0.8127	0.8127
0.9181	0.8262	0.8128	0.8128
0.9141	0.8253	0.8128	0.8128
0.9203	0.8460	0.8130	0.8130
0.9199	0.8415	0.8127	0.8127

`eFolds` is a 5-by-11 matrix of edges. Rows correspond to folds and columns correspond to regularization strengths in `Lambda`. You can use `eFolds` to identify ill-performing folds, that is, unusually low edges.

Estimate the average edge over all folds for each regularization strength.

```
e = kfoldEdge(CVMdl)
```

```
e =
```

```
Columns 1 through 7
```

```
    0.9978    0.9978    0.9978    0.9978    0.9978    0.9935    0.9777
```

```
Columns 8 through 11
```

```
    0.9178    0.8367    0.8128    0.8128
```

Determine how well the models generalize by plotting the averages of the 5-fold edge for each regularization strength. Identify the regularization strength that maximizes the 5-fold edge over the grid.

```
figure;  
plot(log10(Lambda),log10(e),'-o')  
[~, maxEIdx] = max(e);  
maxLambda = Lambda(maxEIdx);  
hold on  
plot(log10(maxLambda),log10(e(maxEIdx)),'ro');  
ylabel('log_{10} 5-fold edge')  
xlabel('log_{10} Lambda')  
legend('Edge','Max edge')  
hold off
```

Several values of Lambda yield similarly high edges. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

```
LambdaFinal = Lambda(5);
```

Train a linear classification model using the entire data set and specify the regularization strength LambdaFinal.

```
MdlFinal = fitlinear(X,Ystats,'ObservationsIn','columns',...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...  
    'Lambda',LambdaFinal);
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Definitions

Classification Edge

The *classification edge* is the weighted mean of the *classification margins*.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The *classification margins* for binary classification are, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The literature commonly defines the margin as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Classification Score

For linear classification models, the raw *classification score* for classifying the observation x , a row vector, into the positive class is defined by

$$f(x_j) = x\beta_j + b_j.$$

For the model with regularization strength j , β_j is the estimated column vector of coefficients (the model property `Beta(:, j)`) and b_j be the estimated, scalar bias (the model property `Bias(j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

`ClassificationLinear` | `ClassificationPartitionedLinear` | `edge` | `kfoldMargin` | `kfoldPredict`

Introduced in R2016a

kfoldEdge

Class: ClassificationPartitionedLinearECOC

Classification edge for observations not used for training

Syntax

```
e = kfoldEdge(CVMdl)
e = kfoldEdge(CVMdl, Name, Value)
```

Description

`e = kfoldEdge(CVMdl)` returns the cross-validated classification edges obtained by the cross-validated, error-correcting output codes (ECOC) model composed of linear classification models `CVMdl`. That is, for every fold, `kfoldEdge` estimates the classification edge for observations that it holds out when it trains using all other observations.

`e` contains a classification edge for each regularization strength in the linear classification models that comprise `CVMdl`.

`e = kfoldEdge(CVMdl, Name, Value)` uses additional options specified by one or more `Name, Value` pair arguments. For example, specify a decoding scheme, which folds to use for the edge calculation, or verbosity level.

Input Arguments

CVMdl — Cross-validated, ECOC model composed of linear classification models

ClassificationPartitionedLinearECOC model object

Cross-validated, ECOC model composed of linear classification models, specified as a ClassificationPartitionedLinearECOC model object. You can create a ClassificationPartitionedLinearECOC model using `fitcecoc` and by:

- 1 Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`

- Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, `ClassificationPartitionedLinearECOC.kfoldEdge` applies the same data used to cross-validate the ECOC model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'`
| `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
<code>'binodeviance'</code>	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
<code>'exponential'</code>	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
<code>'hamming'</code>	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
<code>'hinge'</code>	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
<code>'linear'</code>	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
<code>'logit'</code>	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
<code>'quadratic'</code>	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
where:
```

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 29-4911.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss','binodeviance'`

Data Types: char | function_handle

'Decoding' — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses on page 29-4919, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: char

'Folds' — Fold indices to use for classification-score prediction

1:CVMDL.KFold (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through CVMDL.KFold.

Example: 'Folds',[1 4 10]

Data Types: single | double

'Mode' — Edge aggregation level

'average' (default) | 'individual'

Edge aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

Value	Description
'average'	Returns classification edges averaged over all folds
'individual'	Returns classification edges for each fold

Example: 'Mode','individual'

Data Types: char

'Options' — Estimation options[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options',`statset('UseParallel',1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

e — Cross-validated classification edges

numeric scalar | numeric vector | numeric matrix

Cross-validated classification edges, returned as a numeric scalar, vector, or matrix.

Let L be the number of regularization strengths in the cross-validated models (that is, L is `numel(CVMdl.Trained{1}.BinaryLearners{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is 'average', then \mathbf{e} is a 1-by- L vector. $\mathbf{e}(j)$ is the average classification edge over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, \mathbf{e} is a F -by- L matrix. $\mathbf{e}(i, j)$ is the classification edge for fold i of the cross-validated model that uses regularization strength j .

Examples

Estimate k -Fold Cross-Validation Edge

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Cross-validate a multiclass, linear classification model.

```
rng(1); % For reproducibility
```

```
CVMD1 = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

CVMD1 is a `ClassificationPartitionedLinearECOC` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold edges.

```
e = kfoldEdge(CVMD1)
```

```
e =
```

```
0.7232
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode','individual' in `kfoldEdge`.

Feature Selection Using *k*-fold Edges

One way to perform feature selection is to compare *k*-fold edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set. Preprocess the data as in “Estimate *k*-Fold Cross-Validation Edge”, and orient the predictor data so that observations correspond to columns.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains a 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Create a linear classification model template that specifies to optimize the objective function using `SpaRSA`.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate two ECOC models composed of binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Indicate that observations correspond to columns.

```
CVMD1 = fitcecoc(fullX,Y,'Learners',t,'CrossVal','on',...  
    'ObservationsIn','columns');  
PCVMD1 = fitcecoc(partX,Y,'Learners',t,'CrossVal','on',...  
    'ObservationsIn','columns');
```

CVMD1 and PCVMD1 are ClassificationPartitionedLinearECOC models.

Estimate the k -fold edge for each classifier.

```
fullEdge = kfoldEdge(CVMD1)  
partEdge = kfoldEdge(PCVMD1)
```

```
fullEdge =  
    0.3090
```

```
partEdge =  
    0.2617
```

Based on the k -fold edges, the classifier that uses all of the predictors is the better model.

Find Good Lasso Penalty Using k -fold Edge

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare k -fold edges.

Load the NLP data set. Preprocess the data as in “Feature Selection Using k -fold Edges”.

```
load nlpdata  
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';  
X = X';
```

Create a set of 8 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8,1,8);
```

Create a linear classification model template that specifies to use logistic regression with a lasso penalty, use each of the regularization strengths, optimize the objective function using SpaRSA, and reduce the tolerance on the gradient of the objective function to $1e-8$.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate an ECOC model composed of binary, linear classification models using 5-fold cross-validation and that

```
rng(10); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5)
```

```
CVMdl =
```

```
classreg.learning.partition.ClassificationPartitionedLinearECOC
  CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
  NumObservations: 31572
      KFold: 5
    Partition: [1x1 cvpartition]
    ClassNames: [comm dsp simulink others]
  ScoreTransform: 'none'
```

CVMdl is a ClassificationPartitionedLinearECOC model.

Estimate the edges for each fold and regularization strength.

```
eFolds = kfoldEdge(CVMdl,'Mode','individual')
```

```
eFolds =
```

```
Columns 1 through 7
```

0.5558	0.5554	0.5558	0.5534	0.4956	0.2934	0.1039
0.5248	0.5263	0.5268	0.5274	0.4800	0.2949	0.1045
0.5263	0.5274	0.5280	0.5274	0.4740	0.2891	0.1042
0.5429	0.5445	0.5446	0.5416	0.4878	0.2911	0.1015

```

    0.5505    0.5559    0.5584    0.5578    0.4959    0.2952    0.1021
Column 8
    0.0854
    0.0867
    0.0865
    0.0853
    0.0849

```

`eFolds` is a 5-by-8 matrix of edges. Rows correspond to folds and columns correspond to regularization strengths in `Lambda`. You can use `eFolds` to identify ill-performing folds, that is, unusually low edges.

Estimate the average edge over all folds for each regularization strength.

```
e = kfoldEdge(CVMdl)
```

```

e =
Columns 1 through 7
    0.5401    0.5419    0.5427    0.5415    0.4867    0.2927    0.1032
Column 8
    0.0858

```

Determine how well the models generalize by plotting the averages of the 5-fold edge for each regularization strength. Identify the regularization strength that maximizes the 5-fold edge over the grid.

```

figure;
plot(log10(Lambda),log10(e),'-o')
[~, maxEIdx] = max(e);
maxLambda = Lambda(maxEIdx);
hold on
plot(log10(maxLambda),log10(e(maxEIdx)),'ro');
ylabel('log_{10} 5-fold edge')
xlabel('log_{10} Lambda')
legend('Edge','Max edge')

```

Several values of `Lambda` yield similarly high edges. Greater regularization strength values lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

```
LambdaFinal = Lambda(4);
```

Train an ECOC model composed of linear classification model using the entire data set and specify the regularization strength `LambdaFinal`.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',LambdaFinal,'GradientTolerance',1e-8);
```

```
MdlFinal = fitcecoc(X,Y, 'Learners',t, 'ObservationsIn', 'columns');
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

- “Quick Start Parallel Computing for Statistics and Machine Learning Toolbox” on page 27-2

Definitions

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of predict and loss), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Classification Edge

The *classification edge* is the weighted mean of the *classification margins*.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the true class and maximal negative loss among the false classes. If the margins

are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

kfoldEdge

Class: ClassificationPartitionedModel

Classification edge for observations not used for training

Syntax

```
E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)
```

Description

`E = kfoldEdge(obj)` returns classification edge (average classification margin) obtained by cross-validated classification model `obj`. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

`E = kfoldEdge(obj,Name,Value)` calculates edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

obj

Object of class `ClassificationPartitionedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'folds'

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

Default: `1:obj.KFold`

'mode'

Character vector representing the meaning of the output `edge`:

- `'average'` — `edge` is a scalar value, the average over all folds.
- `'individual'` — `edge` is a vector of length `obj.KFold` with one element per fold.

Default: `'average'`

Output Arguments

E

The average classification margin. `E` is a scalar or vector, depending on the setting of the `mode` name-value pair.

Examples

Estimate the *k*-fold Edge of a Classifier

Compute the *k*-fold edge for a model trained on Fisher's iris data.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree classifier.

```
tree = fitctree(meas,species);
```

Cross validate the classifier using 10-fold cross validation.

```
cvtree = crossval(tree);
```

Compute the k -fold edge.

```
edge = kfoldEdge(cvtree)
```

```
edge =
```

```
0.8578
```

Definitions

Edge

The *edge* is the weighted mean value of the classification *margin*. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X . A high value of margin indicates a more reliable prediction than a low value.

Score

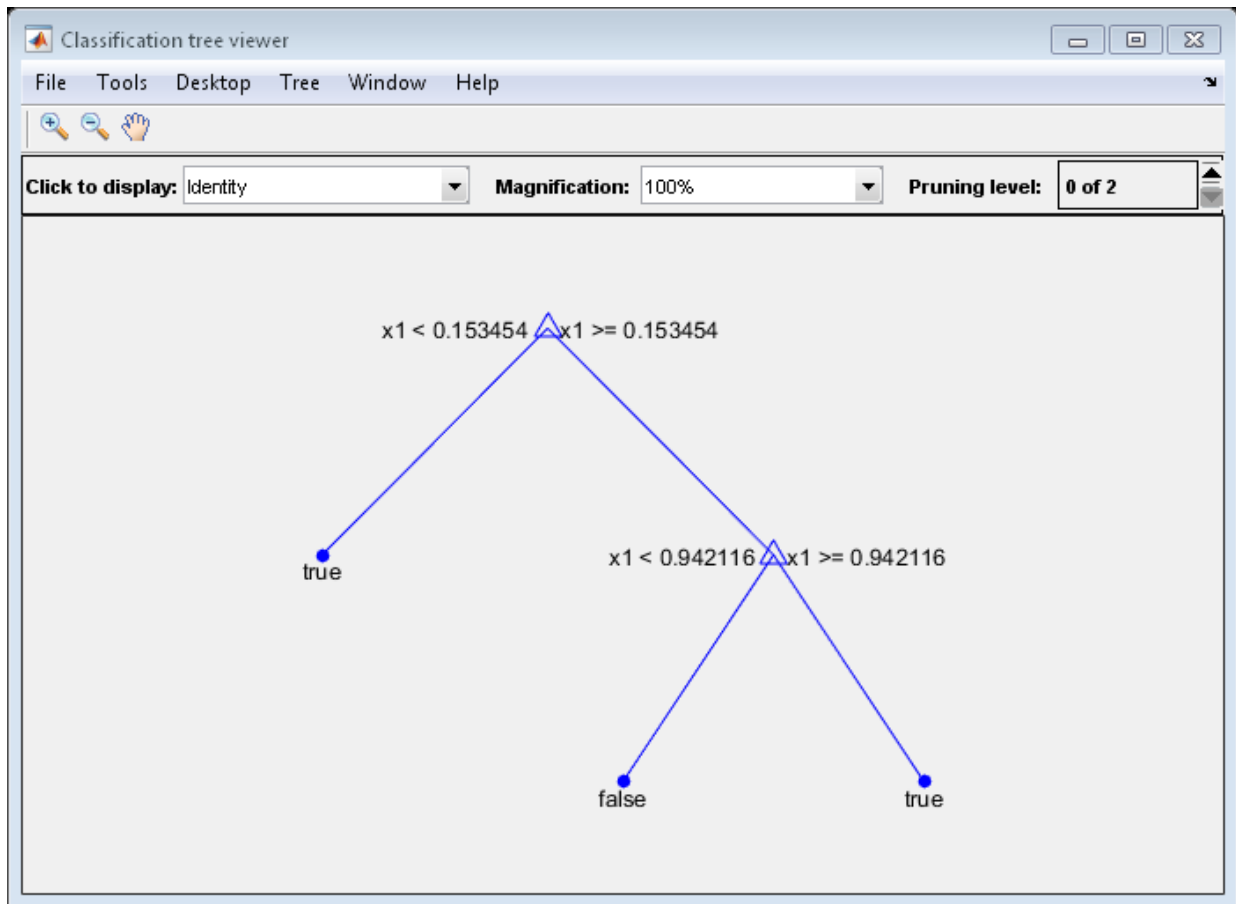

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 17-7.

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as `true` when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

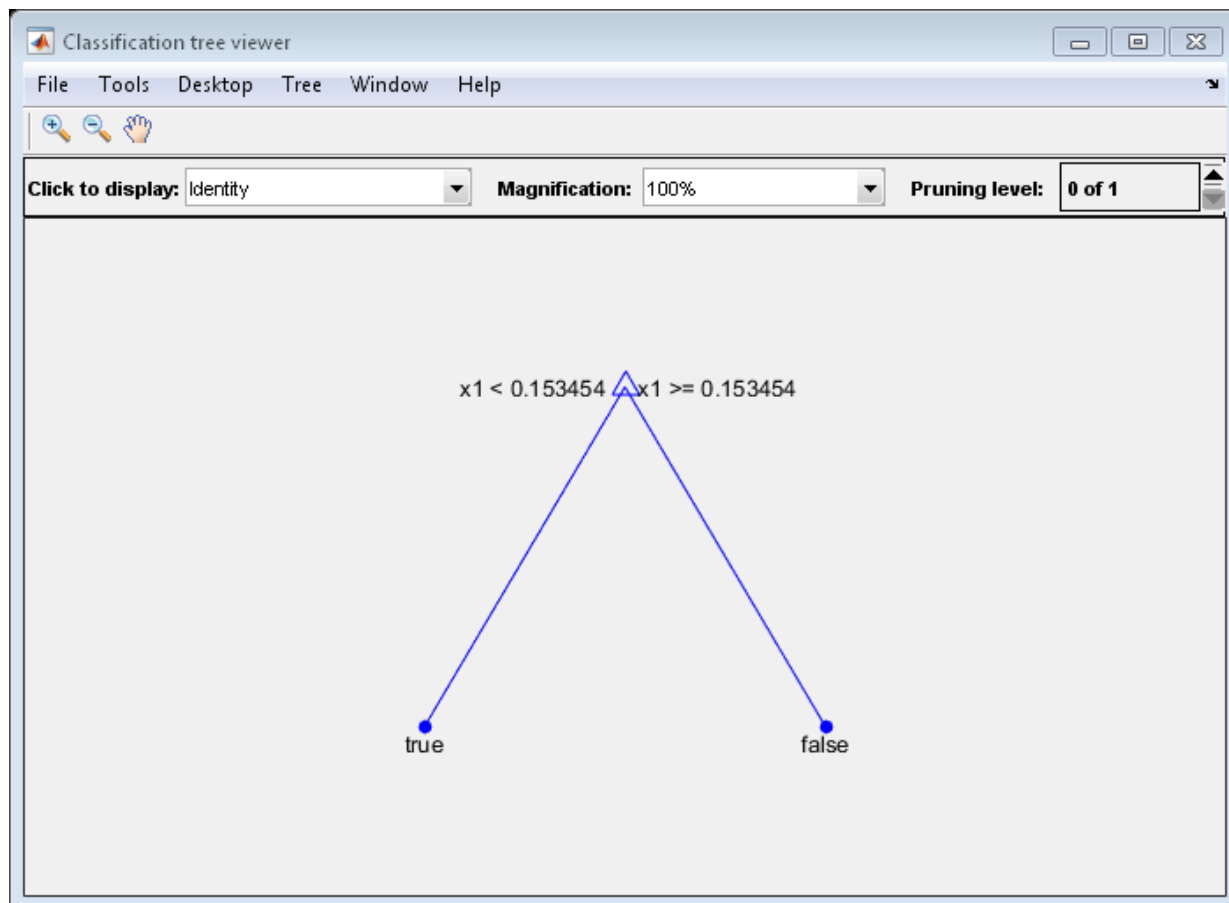

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =  
  0.9059  0.0941  0.8147  
  0.9059  0.0941  0.9058  
    0     1.0000  0.1270  
  0.9059  0.0941  0.9134  
  0.9059  0.0941  0.6324  
    0     1.0000  0.0975  
  0.9059  0.0941  0.2785  
  0.9059  0.0941  0.5469  
  0.9059  0.0941  0.9575  
  0.9059  0.0941  0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Topics

kfoldfun

Class: ClassificationPartitionedECOC

Cross validate function

Syntax

```
vals = kfoldfun(CVMdl, fun)
```

Description

`vals = kfoldfun(CVMdl, fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `CVMdl`. You must pass `fun` as a function handle.

Input Arguments

CVMdl — Cross-validated model

ClassificationPartitionedECOC model |
ClassificationPartitionedEnsemble model |
ClassificationPartitionedModel model

Cross-validated model, specified as a ClassificationPartitionedECOC model, ClassificationPartitionedEnsemble model, or a ClassificationPartitionedModel model.

fun — Cross-validated function

function handle

Cross-validated function, specified as a function handle. `fun` has the syntax

```
testvals = fun(CMP, Xtrain, Ytrain, Wtrain, Xtest, Ytest, Wtest)
```

- `CMP` is a compact model stored in one element of the `CVMdl.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.
- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.

- The returned value `testvals` needs the same size across all folds.

Data Types: `function_handle`

Output Arguments

vals — Cross-validation results

numeric matrix

Cross-validation results, returned as an numeric matrix. `vals` is the arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Data Types: `double`

Examples

Estimate Classification Error Using a Custom Loss Function

Train an ECOC multiclass classifier, and then cross validate it using a custom k -fold loss function.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross validation.

Compute the classification error (proportion of misclassified observations) for the out-of-fold observations.

```
L = kfoldLoss(CVMdl)
```

```
L =
```

```
0.0400
```

Examine the result when the cost of misclassifying a flower as 'versicolor' is 10, and any other error is 1. Write a function called `noversicolor.m` that attributes a cost of 1 for misclassification, but 10 for misclassifying a flower as `versicolor`, and save it on your MATLAB path.

```
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
%noversicolor Example custom cross-validation function
% Attributes a cost of 10 for misclassifying versicolor irises, and 1 for
% the other irises. This example function requires the |fisheriris| data
% set.
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % Different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
cost = sum(misclassified) + ...
    9*sum(misclassified & classifiedAsVersicolor); % Total differences
averageCost = cost/numel(Ytest); % Average error
end
```

Compute the mean misclassification error with the `noversicolor` cost.

```
foldLoss = kfoldfun(CVMdl,@noversicolor);
mean(foldLoss)
```

```
ans =
```

```
0.0667
```

kfoldfun

Class: ClassificationPartitionedModel

Cross validate function

Syntax

```
vals = kfoldfun(CVMd1, fun)
```

Description

`vals = kfoldfun(CVMd1, fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `CVMd1`. You must pass `fun` as a function handle.

Input Arguments

CVMd1 — Cross-validated model

ClassificationPartitionedECOC model |
ClassificationPartitionedEnsemble model |
ClassificationPartitionedModel model

Cross-validated model, specified as a ClassificationPartitionedECOC model, ClassificationPartitionedEnsemble model, or a ClassificationPartitionedModel model.

fun — Cross-validated function

function handle

Cross-validated function, specified as a function handle. `fun` has the syntax

```
testvals = fun(CMP, Xtrain, Ytrain, Wtrain, Xtest, Ytest, Wtest)
```

- `CMP` is a compact model stored in one element of the `CVMd1.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.

- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.
- The returned value `testvals` needs the same size across all folds.

Data Types: `function_handle`

Output Arguments

vals — Cross-validation results

numeric matrix

Cross-validation results, returned as an numeric matrix. `vals` is the arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Data Types: `double`

Examples

Estimate Classification Error Using a Custom Loss Function

Train a classification tree classifier, and then cross validate it using a custom k -fold loss function.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree classifier.

```
Mdl = fitctree(meas,species);
```

`Mdl` is a `ClassificationTree` model.

Cross validate `Mdl` using the default 10-fold cross validation. Compute the classification error (proportion of misclassified observations) for the out-of-fold observations.

```
rng(1); % For reproducibility  
CVMdl = crossval(Mdl);  
L = kfoldLoss(CVMdl)
```

```
L =  
  
    0.0467
```

Examine the result when the cost of misclassifying a flower as 'versicolor' is 10, and any other error is 1. Write a function called `noversicolor.m` that attributes a cost of 1 for misclassification, but 10 for misclassifying a flower as `versicolor`, and save it on your MATLAB path.

```
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)  
%noversicolor Example custom cross-validation function  
%   Attributes a cost of 10 for misclassifying versicolor irises, and 1 for  
%   the other irises. This example function requires the |fisheriris| data  
%   set.  
Ypredict = predict(CMP,Xtest);  
misclassified = not(strcmp(Ypredict,Ytest)); % Different result  
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions  
cost = sum(misclassified) + ...  
    9*sum(misclassified & classifiedAsVersicolor); % Total differences  
averageCost = cost/numel(Ytest); % Average error  
end
```

Compute the mean misclassification error with the `noversicolor` cost.

```
mean(kfoldfun(CVMdl,@noversicolor))  
  
ans =  
  
    0.2267
```

kfoldfun

Class: RegressionPartitionedModel

Cross validate function

Syntax

```
vals = kfoldfun(obj, fun)
```

Description

`vals = kfoldfun(obj, fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `obj`. You must pass `fun` as a function handle.

Input Arguments

obj

Object of class `RegressionPartitionedModel` or `RegressionPartitionedEnsemble`. Create `obj` with `fitrtree` or `fitensemble` along with one of the cross-validation options: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

fun

A function handle for a cross-validation function. `fun` has the syntax

```
testvals = fun(CMP, Xtrain, Ytrain, Wtrain, Xtest, Ytest, Wtest)
```

- `CMP` is a compact model stored in one element of the `obj.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.
- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.

- The returned value `testvals` must have the same size across all folds.

Output Arguments

`vals`

The arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Examples

Cross validate a regression tree, and obtain the mean squared error (see `kfoldLoss`):

```
load imports-85
t = fitrtree(X(:,[4 5]),X(:,16),...
    'predictorNames',{'length' 'width'},...
    'responseName','price');
cv = crossval(t);
L = kfoldLoss(cv)
```

```
L =
    1.5489e+007
```

Examine the result of simple averaging of responses instead of using predictions:

```
f = @(cmp,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)...
    mean((Ytest-mean(Ytrain)).^2)
mean(kfoldfun(cv,f))
```

```
ans =
    6.3497e+007
```

Topics

kfoldLoss

Class: ClassificationPartitionedECOC

Classification loss for observations not used for training

Syntax

```
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

Description

`loss = kfoldLoss(CVMdl)` returns the classification loss obtained by the cross-validated ECOC model (ClassificationPartitionedECOC) `CVMdl`. For every fold, this function computes the classification loss for in-fold observations using a model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

`loss = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the number of folds, decoding scheme, or verbosity level.

Input Arguments

CVMdl — Cross-validated ECOC model

ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a ClassificationPartitionedECOC model. You can create a ClassificationPartitionedECOC model by:

- Passing a trained ECOC model (ClassificationECOC) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition'

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge'
| 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` should have this form:

```
bLoss = customFunction(M,s)
where:
```

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 29-4911.

By default, if all binary learners are:

- SVMs or linear classification models of SVM learners, then `BinaryLoss` is 'hinge'
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is 'exponential'
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is 'binodeviance'
- Linear classification models of logistic regression learners, or you specify to predict class posterior probabilities (i.e., set 'FitPosterior', 1 in `fitcecoc`), then `BinaryLoss` is 'quadratic'

Otherwise, the default `BinaryLoss` is 'hamming'. To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | function_handle

'Decoding' — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses on page 29-4919, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'.

Example: 'Decoding', 'lossbased'

Data Types: char

'Folds' — Fold indices for prediction

1:Mdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of **'Folds'** and a numeric vector of positive integers. The elements of **Folds** must range from 1 through `Mdl.KFold`.

The software only uses the folds specified in **Folds** for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

'LossFun' — Loss function

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of **'LossFun'** and a function handle or **'classiferror'**.

You can:

- Specify the built-in function **'classiferror'**, then the loss function is the classification error
- Specify your own function using function handle notation.

For what follows, n is the number of observations in the training data (`CVMD1.NumObservations`) and K is the number of classes (`numel(CVMD1.ClassNames)`). Your function needs the signature `lossvalue = Lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*Lossfun*).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `CVMD1.ClassNames`.

Construct C by setting $C(p,q) = 1$ if observation p is in class q , for each row. Set every element of row p to 0.

- S is an n -by- K numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in `CVMD1.ClassNames`. S resembles the output argument `NegLoss` of `kfoldPredict`.

- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes its elements to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: `function_handle` | `char`

'Mode' — Edge aggregation level

'average' (default) | 'individual'

Edge meaning, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

Value	Description
'average'	edge is the scalar average over all folds.
'individual'	edge is a vector of length k containing one edge per fold. k is the number of folds.

Example: `'Mode', 'individual'`

Data Types: `char`

'Options' — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options', statset('UseParallel', 1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the amount of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

Output Arguments

loss — Classification loss

numeric scalar | numeric row vector

Classification loss, returned as a numeric scalar or numeric row vector.

If Mode is 'average', then loss is the average classification loss among all binary learners. Otherwise, loss is a 1-by-L numeric row vector containing the classification loss for each, respective binary learner, where L is the number of binary learners (size(CVMdl.CodingMatrix,2)).

Data Types: single | double

Examples

Determine *k*-Fold Cross-Validation Loss of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMD1 = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMD1 is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average out-of-fold classification error.

```
L = kfoldLoss(CVMD1)
```

```
L =
```

```
0.0400
```

The average classification error for the folds is 4%.

Alternatively, you can obtain the per-fold losses by specifying the name-value pair 'Mode','individual' in kfoldLoss.

Display Individual Losses for Each Cross-Validation Fold

The classification loss is a measure of classifier quality. You can determine ill-performing folds by displaying the losses for each fold.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to use 8-fold cross validation. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMD1 = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the average classification loss across folds, and the losses for each fold.

```
loss = kfoldLoss(CVMD1)
```

```
losses = kfoldLoss(CVMdl, 'Mode', 'individual')

loss =

    0.0333

losses =

    0.0556
    0.0526
    0.1579
         0
         0
         0
         0
         0
```

The third fold misclassifies a much higher portion of observations than any other fold.

Return the classification loss for the entire model by specifying the well-performing folds using the 'Folds' name-value pair argument.

```
loss = kfoldLoss(CVMdl, 'Folds', [1:2 4:8])

loss =

    0.0153
```

The total classification loss decreased by approximately half its original size.

Consider adjusting parameters of the binary classifiers or the coding design to see if performance for all folds improves.

Determine ECOC Model Quality Using a Custom Cross-Validation Loss

Suppose that it is interesting to know how well a model classifies a particular class. This example shows how to pass such a custom loss function to `kfoldLoss`.

Load Fisher's iris data set.

```

load fisheriris
X = meas;
Y = categorical(species);
n = numel(Y); % Sample size
classOrder = unique(Y) % Class order
K = numel(classOrder); % Number of classes
rng(1) % For reproducibility

```

```

classOrder =

    3×1 categorical array

    setosa
    versicolor
    virginica

```

Train an ECOC model using SVM binary classifiers, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```

t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);

```

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Compute the negated losses for the out-of-fold observations.

```

[~,negLoss] = kfoldPredict(CVMdl);

```

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations.

```

lossfun = @(C,S,~,~)mean(min(-negLoss,[],2));

```

Compute the cross-validated custom loss.

```

kfoldLoss(CVMdl,'LossFun',lossfun)

```

```

ans =

```

0.0101

The average, minimal, binary loss for the out-of-fold observations is 0.0101.

- “Quick Start Parallel Computing for Statistics and Machine Learning Toolbox” on page 27-2

Definitions

Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation

- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$

Value	Description	Score Domain	$g(y_i, s_i)$
'quadratic'	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the `LossFun` name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

kfoldLoss

Class: ClassificationPartitionedEnsemble

Classification loss for observations not used for training

Syntax

```
L = kfoldLoss(ens)
L = kfoldLoss(ens,Name,Value)
```

Description

`L = kfoldLoss(ens)` returns loss obtained by cross-validated classification model `ens`. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

`L = kfoldLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`ens`

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'folds'

Indices of folds ranging from 1 to `ens.KFold`. Use only these folds for predictions.

Default: `1:ens.KFold`

'lossfun'

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector.

Value	Description
<code>'binodeviance'</code>	Binomial deviance
<code>'classiferror'</code>	Classification error
<code>'exponential'</code>	Exponential
<code>'hinge'</code>	Hinge
<code>'logit'</code>	Logistic
<code>'mincost'</code>	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
<code>'quadratic'</code>	Quadratic

`'mincost'` is appropriate for classification scores that are posterior probabilities.

- Bagged and subspace ensembles return posterior probabilities by default (`ens.Method` is `'Bag'` or `'Subspace'`).
- If the ensemble method is `'AdaBoostM1'`, `'AdaBoostM2'`, `GentleBoost`, or `'LogitBoost'`, then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering

```
ens.ScoreTransform = 'doublelogit';
```
- For all other ensemble methods, the software does not support posterior probabilities as classification scores.
- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(ens.ClassNames)`), `ens` is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- `C` is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `ens.ClassNames`.

Construct `C` by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- `S` is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `ens.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
- `W` is an n -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to 1.
- `Cost` is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 29-3185.

Default: `'classiferror'`

'mode'

A character vector for determining the output of `kfoldLoss`:

- `'average'` — L is a scalar, the loss averaged over all folds.
- `'individual'` — L is a vector of length `ens.KFold`, where each entry is the loss for a fold.
- `'cumulative'` — L is a vector in which element J is obtained by using learners $1:J$ from the input list of learners.

Default: 'average'

Output Arguments

L

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Cross-Validated Classification Error

Load the `ionosphere` data set.

```
load ionosphere
```

Boost 100 trees using `AdaBoostM1`.

```
ens = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
```

Cross-validate the ensemble using 10-fold cross-validation.

```
cvens = crossval(ens);
```

Estimate the cross-validated classification error.

```
L = kfoldLoss(cvens)
```

```
L =
```

```
0.0655
```

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When comparing the same type of loss among many models, lower loss indicates a better predictive model.

Suppose that:

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, and a 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.

- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

The supported loss functions are:

- Binomial deviance, specified using 'LossFun', 'binodeviance'. Its equation is

$$L = \sum_{j=1}^n w_j \log \{1 + \exp[-2m_j]\}.$$

- Exponential loss, specified using 'LossFun', 'exponential'. Its equation is

$$L = \sum_{j=1}^n w_j \exp(-m_j).$$

- Classification error, specified using 'LossFun', 'classiferror'. It is the weighted fraction of misclassified observations, with equation

$$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$$

\hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

- Hinge loss, specified using 'LossFun', 'hinge'. Its equation is

$$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$$

- 29-3186** • Logit loss, specified using 'LossFun', 'logit'. Its equation is

$$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$$

- Minimal cost, specified using 'LossFun', 'mincost'. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$:

- 1 Estimate the 1-by- K vector of expected classification costs for observation j

$$\gamma_j = f(X_j)'C.$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix the input model stores in the property **Cost**.

- 2 For observation j , predict the class label corresponding to the minimum, expected classification cost:

$$\hat{y}_j = \min_{j=1, \dots, K}(\gamma_j).$$

- 3 Using C , identify the cost incurred (c_j) for making the prediction.

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^n w_j c_j.$$

- Quadratic loss, specified using 'LossFun', 'quadratic'. Its equation is

$$L = \sum_{j=1}^n w_j (1 - m_j)^2.$$

This figure compares some of the loss functions for one observation over m (some functions are normalized to pass through $[0, 1]$).

Topics

kfoldLoss

Class: ClassificationPartitionedLinear

Classification loss for observations not used in training

Syntax

```
L = kfoldLoss(CVMd1)
L = kfoldLoss(CVMd1,Name,Value)
```

Description

`L = kfoldLoss(CVMd1)` returns the cross-validated classification losses obtained by the cross-validated, binary, linear classification model `CVMd1`. That is, for every fold, `kfoldLoss` estimates the classification loss for observations that it holds out when it trains using all other observations.

`L` contains a classification loss for each regularization strength in the linear classification models that compose `CVMd1`.

`L = kfoldLoss(CVMd1,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, indicate which folds to use for the loss calculation or specify the classification-loss function.

Input Arguments

CVMd1 — Cross-validated, binary, linear classification model

ClassificationPartitionedLinear model object

Cross-validated, binary, linear classification model, specified as a ClassificationPartitionedLinear model object. You can create a ClassificationPartitionedLinear model using `fitlinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, ClassificationPartitionedLinear.kfoldLoss applies the same data used to cross-validate the linear classification model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Folds' — Fold indices to use for classification-score prediction

1: `CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `CVMdl.KFold`.

Example: 'Folds', [1 4 10]

Data Types: single | double

'LossFun' — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. For linear classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see predict).

- Specify your own function using function handle notation.

Let n be the number of observations in X and K be the number of distinct classes (`numel(Mdl.ClassNames)`, Mdl is the input model). Your function must have this signature

`lossvalue = lossfun(C,S,W,Cost)`

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct C by setting $C(p,q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun',@lossfun`.

Data Types: `char` | `function_handle`

'Mode' — Loss aggregation level

'average' (default) | 'individual'

Loss aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

Value	Description
'average'	Returns losses averaged over all folds
'individual'	Returns losses for each fold

Example: 'Mode', 'individual'

Data Types: char

Output Arguments

L — Cross-validated classification losses

numeric scalar | numeric vector | numeric matrix

Cross-validated classification losses, returned as a numeric scalar, vector, or matrix. The interpretation of L depends on LOSSFun.

Let R be the number of regularizations strengths is the cross-validated models (stored in `numel(CVMdl.Trained{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If Mode is 'average', then L is a 1-by- R vector. $L(j)$ is the average classification loss over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, L is an F -by- R matrix. $L(i, j)$ is the classification loss for fold i of the cross-validated model that uses regularization strength j .

To estimate L, `kfoldLoss` uses the data that created CVMdl (see X and Y).

Examples

Estimate k -Fold Cross-Validation Classification Error

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'CrossVal','on');
```

CVMdl is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold, classification error rates.

```
ce = kfoldLoss(CVMdl)
```

```
ce =
```

```
7.6017e-04
```

Alternatively, you can obtain the per-fold classification error rates by specifying the name-value pair 'Mode', 'individual' in `kfoldLoss`.

Specify Custom Classification Loss

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Classification Error”, and transpose the predictor data.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Cross-validate a binary, linear classification model using 5-fold cross-validation. Optimize the objective function using `SpaRSA`. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','KFold',5,...
    'ObservationsIn','columns');
CMD1 = CVMdl.Trained{1};
```

CVMdl is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 5-by-1 cell array holding a `ClassificationLinear` models that the software trained using the training set of each fold.

Create an anonymous function that measures linear loss, that is,

$$L = \frac{\sum_j -w_j y_j f_j}{\sum_j w_j}.$$

w_j is the weight for observation j , y_j is response j (-1 for the negative class, and 1 otherwise), and f_j is the raw classification score of observation j . Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the `LossFun` name-value pair argument. Because the function does not use classification cost, use `~` to have `kfoldLoss` ignore its position.

```
linearloss = @(C,S,W,~)sum(-W.*sum(S.*C,2))/sum(W);
```

Estimate the average cross-validated classification loss using the linear loss function. Also, obtain the loss for each fold.

```
ce = kfoldLoss(CVMdl,'LossFun',linearloss)
ceFold = kfoldLoss(CVMdl,'LossFun',linearloss,'Mode','individual')
```

```
ce =
    -8.0982
```

```
ceFold =
    -8.3165
    -8.7633
    -7.4342
    -8.0423
    -7.9347
```

Find Good Lasso Penalty Using k -fold Classification Loss

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss”.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Cross-validate binary, linear classification models using 5-fold cross-validation, and that use each of the regularization strengths. Optimize the objective function using SpARSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility
CVMdl = fitlinear(X, Ystats, 'ObservationsIn', 'columns', ...
    'KFold', 5, 'Learner', 'logistic', 'Solver', 'sparsa', ...
    'Regularization', 'lasso', 'Lambda', Lambda, 'GradientTolerance', 1e-8)
```

```
CVMdl =
```

```
classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 5
  Partition: [1×1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'
```

Extract a trained linear classification model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =  
  
ClassificationLinear  
    ResponseName: 'Y'  
    ClassNames: [0 1]  
    ScoreTransform: 'logit'  
        Beta: [34023×11 double]  
        Bias: [1×11 double]  
        Lambda: [1×11 double]  
    Learner: 'logistic'
```

Mdl1 is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of Mdl as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated classification error.

```
ce = kfoldLoss(CVMdl);
```

Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitlinear(X,Ystats,'ObservationsIn','columns',...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...  
    'Lambda',Lambda,'GradientTolerance',1e-8);  
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;  
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...  
    log10(Lambda),log10(numNZCoeff));  
hL1.Marker = 'o';  
hL2.Marker = 'o';  
ylabel(h(1),'log_{10} classification error')
```

```

ylabel(h(2), 'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
title('Test-Sample Statistics')
hold off

```

Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from Mdl with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When comparing the same type of loss among many models, lower loss indicates a better predictive model.

Suppose that:

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, and a 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.

- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

The supported loss functions are:

- Binomial deviance, specified using 'LossFun', 'binodeviance'. Its equation is

$$L = \sum_{j=1}^n w_j \log \{1 + \exp[-2m_j]\}.$$

- Exponential loss, specified using 'LossFun', 'exponential'. Its equation is

$$L = \sum_{j=1}^n w_j \exp(-m_j).$$

- Classification error, specified using 'LossFun', 'classiferror'. It is the weighted fraction of misclassified observations, with equation

$$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$$

\hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

- Hinge loss, specified using 'LossFun', 'hinge'. Its equation is

$$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$$

- Logit loss, specified using 'LossFun', 'logit'. Its equation is

$$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$$

- Minimal cost, specified using 'LossFun', 'mincost'. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$:

- 1 Estimate the 1-by- K vector of expected classification costs for observation j

$$\gamma_j = f(X_j)'C.$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix the input model stores in the property `Cost`.

- 2 For observation j , predict the class label corresponding to the minimum, expected classification cost:

$$\hat{y}_j = \min_{j=1, \dots, K} (\gamma_j).$$

- 3 Using C , identify the cost incurred (c_j) for making the prediction.

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^n w_j c_j.$$

- Quadratic loss, specified using 'LossFun', 'quadratic'. Its equation is

$$L = \sum_{j=1}^n w_j (1 - m_j)^2.$$

This figure compares some of the loss functions for one observation over m (some functions are normalized to pass through $[0, 1]$).

Introduced in R2016a

kfoldLoss

Class: ClassificationPartitionedLinearECOC

Classification loss for observations not used in training

Syntax

`L = kfoldLoss(CVMdl)`

`L = kfoldLoss(CVMdl,Name,Value)`

Description

`L = kfoldLoss(CVMdl)` returns the cross-validated classification error rates estimated by the cross-validated, error-correcting output codes (ECOC) model composed of linear classification models `CVMdl`. That is, for every fold, `kfoldLoss` estimates the classification error rate for observations that it holds out when it trains using all other observations. `kfoldLoss` applies the same data used create `CVMdl` (see `fitcecoc`).

`L` contains a classification loss for each regularization strength in the linear classification models that compose `CVMdl`.

`L = kfoldLoss(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify a decoding scheme, which folds to use for the loss calculation, or verbosity level.

Input Arguments

CVMdl — Cross-validated, ECOC model composed of linear classification models

ClassificationPartitionedLinearECOC model object

Cross-validated, ECOC model composed of linear classification models, specified as a ClassificationPartitionedLinearECOC model object. You can create a ClassificationPartitionedLinearECOC model using `fitcecoc` and by:

- 1 Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`

- 2 Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, `ClassificationPartitionedLinearECOC.kfoldLoss` applies the same data used to cross-validate the ECOC model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'`
| `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
<code>'binodeviance'</code>	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
<code>'exponential'</code>	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
<code>'hamming'</code>	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
<code>'hinge'</code>	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
<code>'linear'</code>	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
<code>'logit'</code>	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
<code>'quadratic'</code>	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
where:
```

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 29-4911.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss','binodeviance'`

Data Types: char | function_handle

'Decoding' — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses on page 29-4919, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: char

'Folds' — Fold indices to use for classification-score prediction

1:CVMD1.KFold (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through CVMD1.KFold.

Example: 'Folds', [1 4 10]

Data Types: single | double

'LossFun' — Loss function

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a function handle or 'classiferror'.

You can:

- Specify the built-in function 'classiferror', then the loss function is the classification error.
- Specify your own function using function handle notation.

For what follows, n is the number of observations in the training data (CVMD1.NumObservations) and K is the number of classes (numel(CVMD1.ClassNames)). Your function needs the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in CVMD1.ClassNames.

Construct C by setting $C(p,q) = 1$ if observation p is in class q , for each row. Set every element of row p to 0.

- S is an n -by- K numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in CVMD1.ClassNames. S resembles the output argument `NegLoss` of `kfoldPredict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes its elements to sum to 1.

- **Cost** is a K-by-K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: `function_handle` | `char`

'Mode' — Loss aggregation level

`'average'` (default) | `'individual'`

Loss aggregation level, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

Value	Description
<code>'average'</code>	Returns losses averaged over all folds
<code>'individual'</code>	Returns losses for each fold

Example: `'Mode', 'individual'`

Data Types: `char`

'Options' — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options', statset('UseParallel', 1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

L — Cross-validated classification losses

numeric scalar | numeric vector | numeric matrix

Cross-validated classification losses, returned as a numeric scalar, vector, or matrix. The interpretation of **L** depends on **LossFun**.

Let R be the number of regularizations strengths is the cross-validated models (`CVMdl.Trained{1}.BinaryLearners{1}.Lambda`) and F be the number of folds (stored in `CVMdl.KFold`).

- If **Mode** is 'average', then **L** is a 1-by- R vector. $L(j)$ is the average classification loss over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, **L** is a F -by- R matrix. $L(i, j)$ is the classification loss for fold i of the cross-validated model that uses regularization strength j .

Examples

Estimate k -Fold Cross-Validation Classification Error

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and **Y** is a categorical vector of class labels.

Cross-validate an ECOC model of linear classification models.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

CVMdl is a **ClassificationPartitionedLinearECOC** model. By default, the software implements 10-fold cross validation.

Estimate the average of the out-of-fold classification error rates.

```
ce = kfoldLoss(CVMdl)
```

```
ce =  
    0.0958
```

Alternatively, you can obtain the per-fold classification error rates by specifying the name-value pair 'Mode', 'individual' in `kfoldLoss`.

Specify Custom Classification Loss

Load the NLP data set. Transpose the predictor data.

```
load nlpdata  
X = X';
```

For simplicity, use the label 'others' for all observations in `Y` that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a linear classification model template that specifies optimizing the objective function using `SpaRSA`.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Optimize the objective function using `SpaRSA`. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility  
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns');  
CMdl1 = CVMdl.Trained{1}
```

```
CMdl1 =  
  
classreg.learning.classif.CompactClassificationECOC  
    ResponseName: 'Y'  
    ClassNames: [comm    dsp    simulink    others]  
    ScoreTransform: 'none'  
    BinaryLearners: {6×1 cell}  
    CodingMatrix: [4×6 double]
```

`CVMD1` is a `ClassificationPartitionedLinearECOC` model. It contains the property `Trained`, which is a 5-by-1 cell array holding a `CompactClassificationECOC` models that the software trained using the training set of each fold.

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations. Because the function does not use the class-identifier matrix (`C`), observation weights (`W`), and classification cost (`Cost`), use `~` to have `kfoldLoss` ignore its their positions.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Estimate the average cross-validated classification loss using the minimal loss per observation function. Also, obtain the loss for each fold.

```
ce = kfoldLoss(CVMD1, 'LossFun', lossfun)
ceFold = kfoldLoss(CVMD1, 'LossFun', lossfun, 'Mode', 'individual')
```

```
ce =
```

```
    0.0243
```

```
ceFold =
```

```
    0.0244
    0.0255
    0.0248
    0.0240
    0.0226
```

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for an ECOC model composed of linear classification models that use logistic regression learners, implement 5-fold cross-validation.

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-7} through 10^{-2} .

```
Lambda = logspace(-7,-2,11);
```

Create a linear classification model template that specifies to use logistic regression learners, use lasso penalties with strengths in `Lambda`, train using `SparSA`, and lower the tolerance on the gradient of the objective function to `1e-8`.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...  
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';  
rng(10); % For reproducibility  
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5);
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model.

Dissect `CVMdl`, and each model within it.

```
numECOCModels = numel(CVMdl.Trained)  
ECOCmdl1 = CVMdl.Trained{1}  
numCLModels = numel(ECOCmdl1.BinaryLearners)  
CLmdl1 = ECOCmdl1.BinaryLearners{1}
```

```
numECOCModels =
```

```
5
```

```
ECOCmdl1 =
```

```
classreg.learning.classif.CompactClassificationECOC  
    ResponseName: 'Y'  
    ClassNames: [comm    dsp    simulink  others]  
    ScoreTransform: 'none'
```

```

BinaryLearners: {6×1 cell}
CodingMatrix: [4×6 double]

numCLModels =

    6

CLMd11 =

ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [-1 1]
    ScoreTransform: 'logit'
        Beta: [34023×11 double]
        Bias: [1×11 double]
        Lambda: [1×11 double]
    Learner: 'logistic'

```

Because `fitcecoc` implements 5-fold cross-validation, `CVMD1` contains a 5-by-1 cell array of `CompactClassificationECOC` models that the software trains on each fold. The `BinaryLearners` property of each `CompactClassificationECOC` model contains the `ClassificationLinear` models. The number of `ClassificationLinear` models within each compact ECOC model depends on the number of distinct labels and coding design. Because `Lambda` is a sequence of regularization strengths, you can think of `CLMd11` as 11 models, one for each regularization strength in `Lambda`.

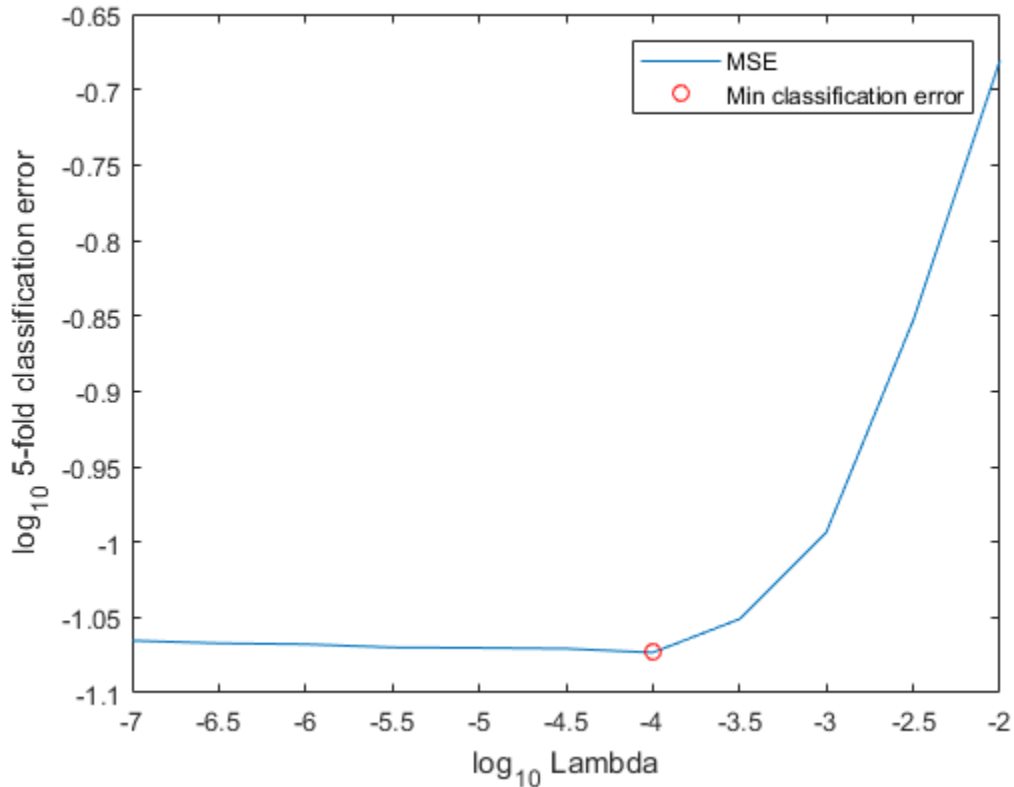

Determine how well the models generalize by plotting the averages of the 5-fold classification error for each regularization strength. Identify the regularization strength that minimizes the generalization error over the grid.

```

ce = kfoldLoss(CVMD1);
figure;
plot(log10(Lambda), log10(ce))
[~, minCEIdx] = min(ce);
minLambda = Lambda(minCEIdx);
hold on
plot(log10(minLambda), log10(ce(minCEIdx)), 'ro');
ylabel('log_{10} 5-fold classification error')
xlabel('log_{10} Lambda')

```

```
legend('MSE', 'Min classification error')
hold off
```

Train an ECOC model composed of linear classification model using the entire data set, and specify the minimal regularization strength.

```
t = templateLinear('Learner', 'logistic', 'Solver', 'sparsa', ...
    'Regularization', 'lasso', 'Lambda', minLambda, 'GradientTolerance', 1e-8);
MdlFinal = fitcecoc(X, Y, 'Learners', t, 'ObservationsIn', 'columns');
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_i, s_i)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_i s_i)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_i s_i) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_i s_i)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_i s_i) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_i s_i) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_i s_i)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_i(2s_i - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the `LossFun` name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

kfoldLoss

Class: ClassificationPartitionedModel

Classification loss for observations not used for training

Syntax

```
L = kfoldLoss(obj)
L = kfoldLoss(obj,Name,Value)
```

Description

`L = kfoldLoss(obj)` returns loss obtained by cross-validated classification model `obj`. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

`L = kfoldLoss(obj,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

obj

Object of class `ClassificationPartitionedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'folds'

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

Default: 1:obj.KFold

'lossfun'

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. All models use posterior probabilities as classification scores by default except SVM models. You can specify to use posterior probabilities as classification scores for SVM models by setting 'FitPosterior', true when you cross-validate the model using `fitcsvm`.

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(obj.ClassNames)`, `obj` is the input model). Your function must have this signature

`lossvalue = lossfun(C,S,W,Cost)`

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).

- **C** is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `obj.ClassNames`.

Construct **C** by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- **S** is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `obj.ClassNames`. **S** is a matrix of classification scores, similar to the output of `predict`.
- **W** is an n -by-1 numeric vector of observation weights. If you pass **W**, the software normalizes them to sum to 1.
- **Cost** is a K -by- K numeric matrix of misclassification costs. For example, **Cost** = `ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 29-3219.

Default: `'classiferror'`

'mode'

A character vector for determining the output of `kfoldLoss`:

- `'average'` — **L** is a scalar, the loss averaged over all folds.
- `'individual'` — **L** is a vector of length `obj.KFold`, where each entry is the loss for a fold.

Default: `'average'`

Output Arguments

L

Loss, by default the fraction of misclassified data. **L** can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Cross-Validated Classification Error

Load the ionosphere data set.

```
load ionosphere
```

Grow a classification tree.

```
tree = fitctree(X,Y);
```

Cross-validate the classification tree using 10-fold cross-validation.

```
cvtree = crossval(tree);
```

Estimate the cross-validated classification error.

```
L = kfoldLoss(cvtree)
```

```
L =
```

```
    0.1111
```

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When comparing the same type of loss among many models, lower loss indicates a better predictive model.

Suppose that:

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 indicating the negative or positive class, respectively.

- $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, and a 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^{*'} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

The supported loss functions are:

- Binomial deviance, specified using `'LossFun', 'binodeviance'`. Its equation is

$$L = \sum_{j=1}^n w_j \log \{1 + \exp[-2m_j]\}.$$

- Exponential loss, specified using `'LossFun', 'exponential'`. Its equation is

$$L = \sum_{j=1}^n w_j \exp(-m_j).$$

- Classification error, specified using 'LossFun', 'classiferror'. It is the weighted fraction of misclassified observations, with equation

$$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$$

\hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

- Hinge loss, specified using 'LossFun', 'hinge'. Its equation is

$$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$$

- Logit loss, specified using 'LossFun', 'logit'. Its equation is

$$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$$

- Minimal cost, specified using 'LossFun', 'mincost'. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$:

- 1 Estimate the 1-by- K vector of expected classification costs for observation j

$$\gamma_j = f(X_j)'C.$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix the input model stores in the property **Cost**.

- 2 For observation j , predict the class label corresponding to the minimum, expected classification cost:

$$\hat{y}_j = \min_{j=1, \dots, K}(\gamma_j).$$

29-3221

- 3 Using C , identify the cost incurred (c_j) for making the prediction.

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^n w_j c_j.$$

- Quadratic loss, specified using 'LossFun', 'quadratic'. Its equation is

$$L = \sum_{j=1}^n w_j (1 - m_j)^2.$$

This figure compares some of the loss functions for one observation over m (some functions are normalized to pass through $[0,1]$).

“Examine Quality of KNN Classifier” on page 18-31

kfoldLoss

Class: RegressionPartitionedEnsemble

Cross-validation loss of partitioned regression ensemble

Syntax

```
L = kfoldLoss(cvens)
L = kfoldLoss(cvens, Name, Value)
```

Description

`L = kfoldLoss(cvens)` returns the cross-validation loss of `cvens`.

`L = kfoldLoss(cvens, Name, Value)` returns cross-validation loss with additional options specified by one or more `Name, Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

cvens

Object of class `RegressionPartitionedEnsemble`. Create `obj` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `obj` from a regression ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'folds'

Indices of folds ranging from 1 to `cvens.KFold`. Use only these folds for predictions.

Default: `1:cvens.KFold`

'lossfun'

Function handle for loss function, or `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `LOSS` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: `'mse'`

'mode'

Character vector representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments

L

The loss (mean squared error) between the observations in a fold when compared against predictions made with an ensemble trained on the out-of-fold data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Find the cross-validation loss for a regression ensemble of the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
rens = fitensemble(X,MPG,'LSboost',100,'Tree');
cvrens = crossval(rens);
L = kfoldLoss(cvrens)
```

```
L =
    25.6935
```

Topics

kfoldLoss

Class: RegressionPartitionedLinear

Regression loss for observations not used in training

Syntax

```
L = kfoldLoss(CVMd1)
L = kfoldLoss(CVMd1, Name, Value)
```

Description

Description

`L = kfoldLoss(CVMd1)` returns the cross-validated mean squared error (MSE) obtained by the cross-validated, linear regression model `CVMd1`. That is, for every fold, `kfoldLoss` estimates the regression loss for observations that it holds out when it trains using all other observations.

`L` contains a regression loss for each regularization strength in the linear regression models that compose `CVMd1`.

`L = kfoldLoss(CVMd1, Name, Value)` uses additional options specified by one or more `Name, Value` pair arguments. For example, indicate which folds to use for the loss calculation or specify the regression-loss function.

Input Arguments

CVMd1 — Cross-validated, linear regression model

RegressionPartitionedLinear model object

Cross-validated, linear regression model, specified as a `RegressionPartitionedLinear` model object. You can create a `RegressionPartitionedLinear` model using `fitrlinear` and specifying any of the one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, `RegressionPartitionedLinear.kfoldLoss` applies the same data used to cross-validate the linear regression model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Folds' — Fold indices to use for response prediction

1: `CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices to use for response prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `CVMdl.KFold`.

Example: 'Folds', [1 4 10]

Data Types: `single` | `double`

'LossFun' — Loss function

'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LOSSFUN' and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector. Also, in the table, $f(x) = \beta'x + b$.
 - β is a vector of p coefficients.
 - x is an observation from p predictor variables.
 - b is the scalar bias.

Value	Description
'epsiloninsensitive'	Epsilon-insensitive loss: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$
'mse'	MSE: $\ell[y, f(x)] = [y - f(x)]^2$

'epsiloninsensitive' is appropriate for SVM learners only.

- Specify your own function using function handle notation.

Let n be the number of observations in X . Your function must have this signature

```
lossvalue = lossfun(Y,Yhat,W)
where:
```

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- Y is an n -dimensional vector of observed responses. `RegressionPartitionedLinear.kfoldLoss` passes the input argument Y in for Y .
- $Yhat$ is an n -dimensional vector of predicted responses, which is similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights.

Specify your function using 'LossFun', @`lossfun`.

Data Types: char | function_handle

'Mode' — Loss aggregation level

'average' (default) | 'individual'

Loss aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

Value	Description
'average'	Returns losses averaged over all folds
'individual'	Returns losses for each fold

Example: 'Mode', 'individual'

Data Types: char

Output Arguments

L — Cross-validated regression losses

numeric scalar | numeric vector | numeric matrix

Cross-validated regression losses, returned as a numeric scalar, vector, or matrix. The interpretation of L depends on `LossFun`.

Let R be the number of regularizations strengths is the cross-validated models (stored in `numel(CVMdl.Trained{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is 'average', then L is a 1-by- R vector. $L(j)$ is the average regression loss over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, L is an F -by- R matrix. $L(i, j)$ is the regression loss for fold i of the cross-validated model that uses regularization strength j .

To estimate L, `kfoldLoss` uses the data that created `CVMdl` (see X and Y).

Examples

Estimate k -Fold Mean Squared Error

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Cross-validate a linear regression model using SVM learners.

```
rng(1); % For reproducibility
CVMdl = fitrlinear(X,Y,'CrossVal','on');
```

CVMdl is a `RegressionPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the test-sample MSEs.

```
mse = kfoldLoss(CVMdl)
```

```
mse =
```

```
0.1735
```

Alternatively, you can obtain the per-fold MSEs by specifying the name-value pair 'Mode', 'individual' in `kfoldLoss`.

Specify Custom Regression Loss

Simulate data as in “Estimate k-Fold Mean Squared Error”.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
X = X'; % Put observations in columns for faster training
```

Cross-validate a linear regression model using 10-fold cross-validation. Optimize the objective function using `Sparse`.

```
CVMdl = fitrlinear(X,Y,'CrossVal','on','ObservationsIn','columns',...
    'Solver','sparsa');
```

CVMdl is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 10-by-1 cell array holding `RegressionLinear` models that the software trained using the training set.

Create an anonymous function that measures Huber loss ($\delta = 1$), that is,

$$L = \frac{1}{\sum w_j} \sum_{j=1}^n w_j \ell_j, \text{ where}$$

$$\ell_j = \begin{cases} 0.5\hat{e}^2 & \text{for } |\hat{e}| \leq 1 \\ |\hat{e}| - 0.5 & \text{otherwise} \end{cases} .$$

\hat{e}_j is the residual for observation j . Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the `LOSSFUN` name-value pair argument.

```
huberloss = @(Y,Yhat,W) sum(W.*((0.5*(abs(Y-Yhat)<=1).*(Y-Yhat).^2) + ...
    ((abs(Y-Yhat)>1).*abs(Y-Yhat)-0.5)))/sum(W);
```

Estimate the average Huber loss over the folds. Also, obtain the Huber loss for each fold.

```
mseAve = kfoldLoss(CVMdl, 'LossFun', huberloss)
mseFold = kfoldLoss(CVMdl, 'LossFun', huberloss, 'Mode', 'individual')
```

```
mseAve =
    -0.4447
```

```
mseFold =
    -0.4454
    -0.4479
    -0.4454
    -0.4468
    -0.4435
    -0.4429
    -0.4461
    -0.4422
    -0.4440
    -0.4427
```

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1} .

```
Lambda = logspace(-5,-1,15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using SpARSA.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
```

```
numCLModels = numel(CVMdl.Trained)
```

```
numCLModels =
```

```
5
```

CVMdl is a `RegressionPartitionedLinear` model. Because `fitrlinear` implements 5-fold cross-validation, CVMdl contains 5 `RegressionLinear` models that the software trains on each fold.

Display the first trained linear regression model.

```
Mdl1 = CVMdl.Trained{1}

Mdl1 =

  RegressionLinear
    ResponseName: 'Y'
    ResponseTransform: 'none'
    Beta: [1000×15 double]
    Bias: [1×15 double]
    Lambda: [1×15 double]
    Learner: 'leastsquares'
```

Mdl1 is a `RegressionLinear` model object. `fitrlinear` constructed Mdl1 by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of Mdl1 as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated MSE.

```
mse = kfoldLoss(CVMdl);
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log10 MSE')
ylabel(h(2),'log10 nonzero-coefficient frequency')
xlabel('log10 Lambda')
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, $\text{Lambda}(10)$).

```
idxFinal = 10;
```

Extract the model with corresponding to the minimal MSE.

```
MdlFinal = selectModels(Mdl,idxFinal)
idxNZCoeff = find(MdlFinal.Beta~=0)
EstCoeff = Mdl.Beta(idxNZCoeff)
```

```
MdlFinal =
```

```
RegressionLinear
  ResponseName: 'Y'
  ResponseTransform: 'none'
    Beta: [1000×1 double]
    Bias: -0.0050
    Lambda: 0.0037
  Learner: 'leastsqares'
```

```
idxNZCoeff =
```

```
100
200
```

```
EstCoeff =
```

```
1.0051
1.9965
```

`MdlFinal` is a `RegressionLinear` model with one regularization strength. The nonzero coefficients `EstCoeff` are close to the coefficients that simulated the data.

`kfoldPredict` | `loss` | `RegressionLinear` | `RegressionPartitionedLinear`

Introduced in R2016a

kfoldLoss

Class: RegressionPartitionedModel

Cross-validation loss of partitioned regression model

Syntax

```
L = kfoldLoss(cvmodel)
L = kfoldLoss(cvmodel,Name,Value)
```

Description

`L = kfoldLoss(cvmodel)` returns the cross-validation loss of `cvmodel`.

`L = kfoldLoss(cvmodel,Name,Value)` returns cross-validation loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`cvmodel`

Object of class `RegressionPartitionedModel`. Create `obj` with `fitrtree` along with one of the cross-validation options: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Alternatively, create `obj` from a regression tree with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'folds'`

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

Default: `1:obj.KFold`

'lossfun'

Function handle for loss function or `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `kfoldLoss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: `'mse'`

'mode'

One of the following:

- `'average'` — `L` is the average loss over all folds.
- `'individual'` — `L` is a vector of the individual losses of in-fold observations trained on out-of-fold data.

Default: `'average'`

Output Arguments

L

The loss (mean squared error) between the observations in a fold when compared against predictions made with a tree trained on the out-of-fold data. If `mode` is `'individual'`, `L` is a vector of the losses. If `mode` is `'average'`, `L` is the average loss.

Examples

Construct a partitioned regression model, and examine the cross-validation losses for the folds:

```
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
cvmodel = fitrtree(XX,YY,'crossval','on');
L = kfoldLoss(cvmodel,'mode','individual')
```

```
L =
    44.9635
    11.8525
    18.2046
     9.2965
    29.4329
    54.8659
    24.6446
     8.2085
    19.7593
    16.7394
```

Alternatives

You can avoid constructing a cross-validated tree model by calling `cvLoss` instead of `kfoldLoss`. The cross-validated tree can save time if you are going to examine it more than once.

Topics

kfoldMargin

Class: ClassificationPartitionedECOC

Classification margins for observations not used for training

Syntax

```
margin = kfoldMargin(CVMdl)
margin = kfoldMargin(CVMdl,Name,Value)
```

Description

`margin = kfoldMargin(CVMdl)` returns classification margins obtained by the cross-validated ECOC model (ClassificationPartitionedECOC) `CVMdl`. For every fold, this method computes classification margins for in-fold observations using a model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

`margin = kfoldMargin(CVMdl,Name,Value)` returns classification margins with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the binary learner loss function, decoding scheme, or verbosity level.

Input Arguments

CVMdl — Cross-validated ECOC model

ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a ClassificationPartitionedECOC model. You can create a ClassificationPartitionedECOC model by:

- Passing a trained ECOC model (ClassificationECOC) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge'
| 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` should have this form:

```
bLoss = customFunction(M,s)
where:
```

- *M* is the *K*-by-*L* coding matrix stored in `Mdl.CodingMatrix`.
- *s* is the 1-by-*L* row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- *K* is the number of classes.
- *L* is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 29-4911.

By default, if all binary learners are:

- SVMs or linear classification models of SVM learners, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`
- Linear classification models of logistic regression learners, or you specify to predict class posterior probabilities (i.e., set `'FitPosterior',1` in `fitcecoc`), then `BinaryLoss` is `'quadratic'`

Otherwise, the default `BinaryLoss` is `'hamming'`. To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `function_handle`

'Decoding' — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses on page 29-4919, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: `char`

'Options' — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

margin — Classification margins

numeric vector

Classification margins, returned as a numeric vector. `margin` is an `n`-by-1 vector, where each row is the margin of the corresponding observation, and `n` is the number of observations (i.e., `size(CVMdl.X,1)`).

Data Types: `single` | `double`

Examples

Estimate *k*-Fold Cross-Validated Margins of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the out-of-fold margins. Display the distribution of the `mnargins` using a boxplot.

```
margin = kfoldMargin(CVMdl);

figure;
boxplot(margin);
title('Cross-Validated Margins')
```

An observation margin is the positive-class, negated loss minus the maximum negative-class, negated loss. Classifiers that yield relatively large margins are desirable.

Select ECOC Model Features by Comparing Cross-Validation Margins

The classifier margin measures the average of the classifier margins. One way to perform feature selection is to compare cross-validation margins from multiple models. Based solely on this criterion, the classifier with the greater margins is the best classifier.

Load Fisher's iris data set.

```
load fisheriris  
X = meas;
```

```
Y = categorical(species);  
classOrder = unique(Y); % Class order  
rng(1); % For reproducibility
```

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the petal dimensions.

```
fullX = X;  
partX = X(:,3:4);
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);  
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...  
    'ClassNames',classOrder);  
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...  
    'ClassNames',classOrder);
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedECOC` models. By default, the software implements 10-fold cross validation.

Estimate the test sample margin for each classifier. Specify to use loss-based decoding for aggregating the binary learner results. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = kfoldMargin(CVMdl,'Decoding','lossbased');  
partMargins = kfoldMargin(PCVMdl,'Decoding','lossbased');  
  
figure;  
boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'});  
title('Boxplots of Cross-Validated Margins')
```

The margin distributions are approximately the same, but PCVMd1 is a less complex model, which might make it more desirable.

- “Quick Start Parallel Computing for Statistics and Machine Learning Toolbox” on page 27-2

Definitions

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the true class and maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the `LossFun` name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

kfoldMargin

Class: ClassificationPartitionedLinear

Classification margins for observations not used in training

Syntax

```
m = kfoldMargin(CVMdl)
```

Description

`m = kfoldMargin(CVMdl)` returns the cross-validated classification margins obtained by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldMargin` estimates the classification margins for observations that it holds out when it trains using all other observations.

`m` contains classification margins for each regularization strength in the linear classification models that comprise `CVMdl`.

Input Arguments

CVMdl — Cross-validated, binary, linear classification model

ClassificationPartitionedLinear model object

Cross-validated, binary, linear classification model, specified as a ClassificationPartitionedLinear model object. You can create a ClassificationPartitionedLinear model using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, ClassificationPartitionedLinear.kfoldMargin applies the same data used to cross-validate the linear classification model (X and Y).

Output Arguments

m — Cross-validated classification margins

numeric vector | numeric matrix

Cross-validated classification margins, returned as a numeric vector or matrix.

m is n -by- L , where n is the number of observations in the data that created `CVMD1` (see `X` and `Y`) and L is the number of regularization strengths in `CVMD1` (that is, `numel(CVMD1.Trained{1}.Lambda)`).

$m(i, j)$ is the cross-validated classification margin of observation i using the linear classification model that has regularization strength `CVMD1.Trained{1}.Lambda(j)`.

Data Types: `single` | `double`

Examples

Estimate k -Fold Cross-Validation Margins

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMD1 = fitclinear(X, Ystats, 'CrossVal', 'on');
```

`CVMD1` is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the cross-validated margins.

```
m = kfoldMargin(CVMdl);  
size(m)
```

```
ans =
```

```
    31572         1
```

m is a 31572-by-1 vector. $m(j)$ is the average of the out-of-fold margins for observation j .

Plot the k -fold margins using box plots.

```
figure;  
boxplot(m);  
h = gca;  
h.YLim = [-5 30];  
title('Distribution of Cross-Validated Margins')
```

Feature Selection Using k -fold Margins

One way to perform feature selection is to compare k -fold margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in “Estimate k -Fold Cross-Validation Margins”.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Cross-validate two binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Optimize the objective function using `SparSA`, and indicate that observations correspond to columns.

```
CVMD1 = fitlinear(fullX,Ystats,'CrossVal','on','Solver','sparsa',...
    'ObservationsIn','columns');
PCVMD1 = fitlinear(partX,Ystats,'CrossVal','on','Solver','sparsa',...
    'ObservationsIn','columns');
```

`CVMD1` and `PCVMD1` are `ClassificationPartitionedLinear` models.

Estimate the k -fold margins for each classifier. Plot the distribution of the k -fold margins sets using box plots.

```
fullMargins = kfoldMargin(CVMD1);
partMargins = kfoldMargin(PCVMD1);

figure;
boxplot([fullMargins partMargins],'Labels',...
    {'All Predictors','Half of the Predictors'});
h = gca;
h.YLim = [-30 60];
title('Distribution of Cross-Validated Margins')
```

The distributions of the margins of the two classifiers are similar.

Find Good Lasso Penalty Using k -fold Margins

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of k -fold margins.

Load the NLP data set. Preprocess the data as in “Estimate k -Fold Cross-Validation Margins”.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8,1,11);
```

Cross-validate a binary, linear classification model using 5-fold cross-validation and that uses each of the regularization strengths. Optimize the objective function using SpARSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility
CVMdl = fitlinear(X,Ystats,'ObservationsIn','columns','KFold',5,...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8)
```

```
CVMdl =
```

```
classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
  NumObservations: 31572
    KFold: 5
    Partition: [1×1 cvpartition]
    ClassNames: [0 1]
  ScoreTransform: 'none'
```

CVMdl is a `ClassificationPartitionedLinear` model. Because `fitlinear` implements 5-fold cross-validation, CVMdl contains 5 `ClassificationLinear` models that the software trains on each fold.

Estimate the k -fold margins for each regularization strength.

```
m = kfoldMargin(CVMdl);
size(m)
```

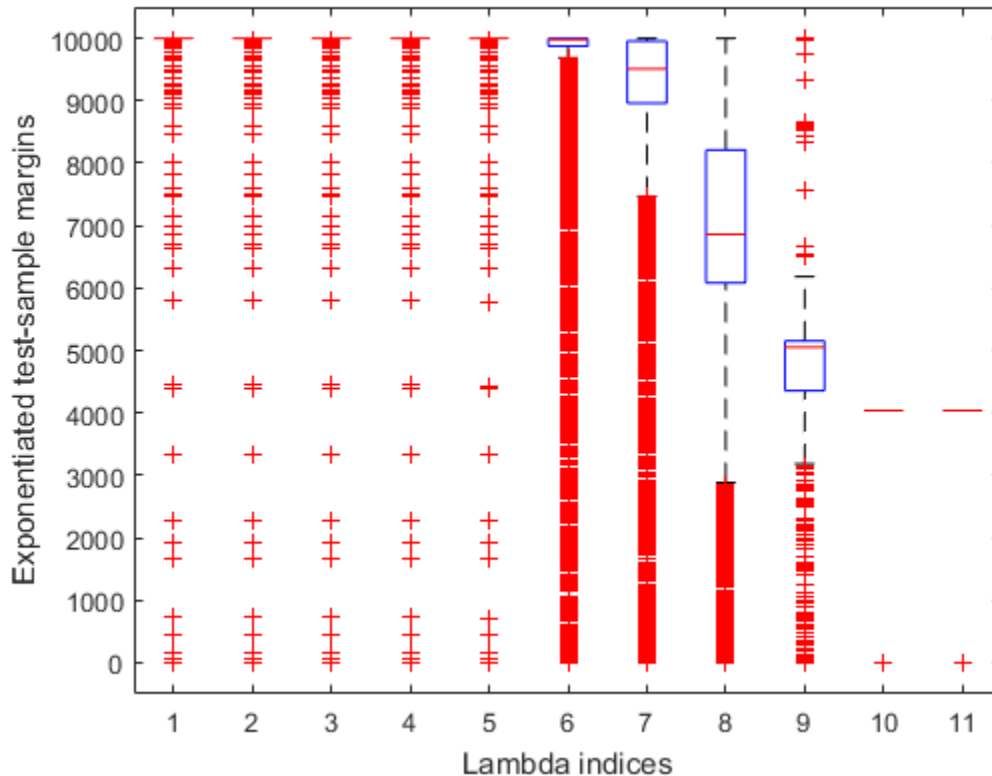

```
ans =
```

```
31572    11
```

`m` is a 31572-by-11 matrix of cross-validated margins for each observation. The columns correspond to the regularization strengths.

Plot the k -fold margins for each regularization strength. Because logistic regression scores are in $[0,1]$, margins are in $[-1,1]$. Rescale the margins to help identify the regularization strength that maximizes the margins over the grid.

```
figure;
boxplot(10000.^m)
ylabel('Exponentiated test-sample margins')
xlabel('Lambda indices')
```

Several values of `Lambda` yield k -fold margin distributions that are compacted near 10000^1 . Higher values of `lambda` lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the centers of the k -fold margin distributions start decreasing.

```
LambdaFinal = Lambda(5);
```

Train a linear classification model using the entire data set and specify the desired regularization strength.

```
MdlFinal = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',LambdaFinal);
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Definitions

Classification Margin

The *classification margins* for binary classification are, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The literature commonly defines the margin as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Classification Score

For linear classification models, the raw *classification score* for classifying the observation x , a row vector, into the positive class is defined by

$$f(x_j) = x\beta_j + b_j.$$

For the model with regularization strength j , β_j is the estimated column vector of coefficients (the model property `Beta(:, j)`) and b_j be the estimated, scalar bias (the model property `Bias(j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Introduced in R2016a

kfoldMargin

Class: ClassificationPartitionedLinearECOC

Classification margins for observations not used in training

Syntax

```
m = kfoldMargin(CVMdl)
m = kfoldMargin(CVMdl,Name,Value)
```

Description

`m = kfoldMargin(CVMdl)` returns the cross-validated classification margins obtained by `CVMdl`, which is a cross-validated, error-correcting output codes (ECOC) model composed of linear classification models. That is, for every fold, `kfoldMargin` estimates the classification margins for observations that it holds out when it trains using all other observations.

`m` contains classification margins for each regularization strength in the linear classification models that comprise `CVMdl`.

`m = kfoldMargin(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify a decoding scheme or verbosity level.

Input Arguments

CVMdl — Cross-validated, ECOC model composed of linear classification models

ClassificationPartitionedLinearECOC model object

Cross-validated, ECOC model composed of linear classification models, specified as a ClassificationPartitionedLinearECOC model object. You can create a ClassificationPartitionedLinearECOC model using `fitcecoc` and by:

- 1 Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`

- 2 Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, `ClassificationPartitionedLinearECOC.kfoldMargin` applies the same data used to cross-validate the ECOC model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'`
| `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
<code>'binodeviance'</code>	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
<code>'exponential'</code>	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
<code>'hamming'</code>	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
<code>'hinge'</code>	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
<code>'linear'</code>	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
<code>'logit'</code>	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
<code>'quadratic'</code>	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
where:
```

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 29-4911.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss','binodeviance'`

Data Types: char | function_handle

'Decoding' — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses on page 29-4919, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: char

'Options' — Estimation options[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`m` — Cross-validated classification margins

numeric vector | numeric matrix

Cross-validated classification margins, returned as a numeric vector or matrix.

`m` is n -by- L , where n is the number of observations in `X` and L is the number of regularization strengths in `Mdl` (that is, `numel(Mdl.Lambda)`).

`m(i,j)` is the cross-validated classification margin of observation i using the ECOC model, composed of linear classification models, that has regularization strength `Mdl.Lambda(j)`.

Examples

Estimate k -Fold Cross-Validation Margins

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Cross-validate a multiclass, linear classification model.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

CVMdl is a ClassificationPartitionedLinearECOC model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the k -fold margins.

```
m = kfoldMargin(CVMdl);
size(m)
```

```
ans =
```

```
    31572         1
```

m is a 31572-by-1 vector. $m(j)$ is the average of the out-of-fold margins for observation j .

Plot the k -fold margins using box plots.

```
figure;
boxplot(m);
h = gca;
```

```
h.YLim = [-5 5];  
title('Distribution of Cross-Validated Margins')
```

Feature Selection Using k -fold Margins

One way to perform feature selection is to compare k -fold margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in “Estimate k -Fold Cross-Validation Margins”, and orient the predictor data so that observations correspond to columns.

```
load nlpdata
```

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Create a linear classification model template that specifies optimizing the objective function using SpARSA.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate two ECOC models composed of binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Indicate that observations correspond to columns.

```
CVMD1 = fitcecoc(fullX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
PCVMD1 = fitcecoc(partX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
```

CVMD1 and PCVMD1 are `ClassificationPartitionedLinearECOC` models.

Estimate the k -fold margins for each classifier. Plot the distribution of the k -fold margins sets using box plots.

```
fullMargins = kfoldMargin(CVMD1);
partMargins = kfoldMargin(PCVMD1);

figure;
boxplot([fullMargins partMargins],'Labels',...
    {'All Predictors','Half of the Predictors'});
h = gca;
h.YLim = [-1 1];
title('Distribution of Cross-Validated Margins')
```

The distributions of the k -fold margins of the two classifiers are similar.

Find Good Lasso Penalty Using k -fold Margins

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of k -fold margins.

Load the NLP data set. Preprocess the data as in “Feature Selection Using k -fold Margins”.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8,1,11);
```

Create a linear classification model template that specifies using logistic regression with a lasso penalty, using each of the regularization strengths, optimizing the objective function using SpARSA, and reducing the tolerance on the gradient of the objective function to $1e-8$.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate an ECOC model composed of binary, linear classification models using 5-fold cross-validation and that

```
rng(10); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5)
```

```
CVMdl =
```

```
classreg.learning.partition.ClassificationPartitionedLinearECOC
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 5
  Partition: [1x1 cvpartition]
  ClassNames: [comm dsp simulink others]
  ScoreTransform: 'none'
```

CVMdl is a ClassificationPartitionedLinearECOC model.

Estimate the k -fold margins for each regularization strength. The scores for logistic regression are in [0,1]. Apply the quadratic binary loss.

```
m = kfoldMargin(CVMdl,'BinaryLoss','quadratic');
size(m)
```

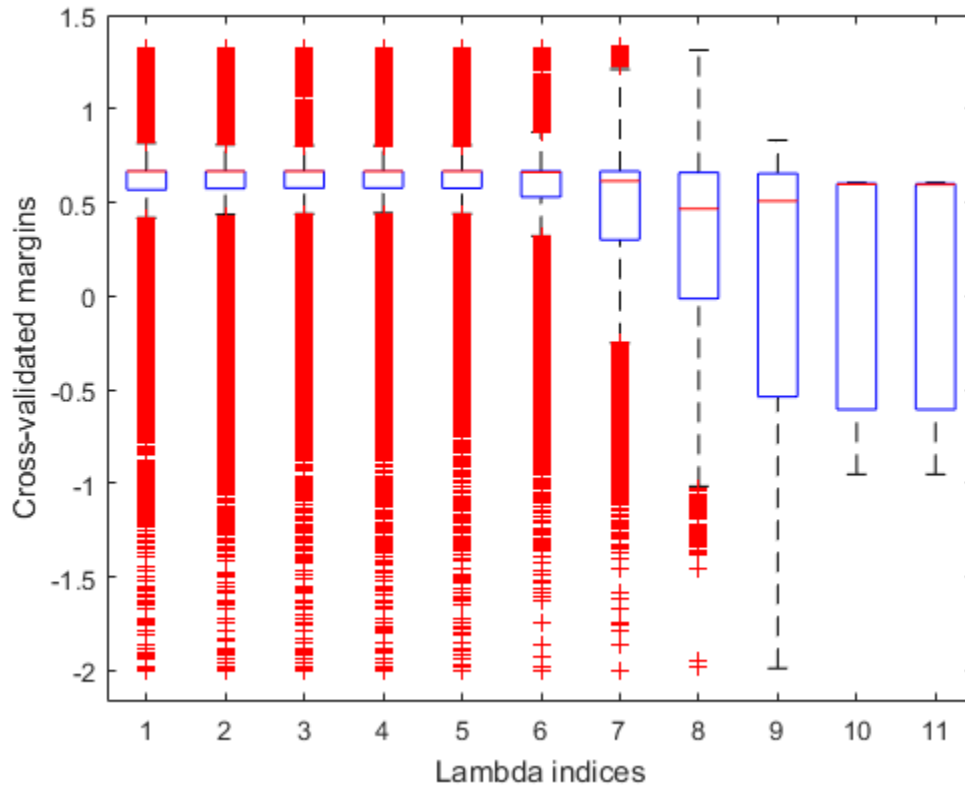

```
ans =
```

```
31572    11
```

`m` is a 31572-by-11 matrix of cross-validated margins for each observation. The columns correspond to the regularization strengths.

Plot the k -fold margins for each regularization strength.

```
figure;  
boxplot(m)  
ylabel('Cross-validated margins')  
xlabel('Lambda indices')
```

Several values of `Lambda` yield similarly high margin distribution centers with low spreads. Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the margin distribution center starts decreasing and spread starts increasing.

```
LambdaFinal = Lambda(5);
```

Train an ECOC model composed of linear classification model using the entire data set and specify the regularization strength `LambdaFinal`.

```
t = templateLinear('Learner', 'logistic', 'Solver', 'sparsa', ...
    'Regularization', 'lasso', 'Lambda', Lambda(5), 'GradientTolerance', 1e-8);
MdlFinal = fitcecoc(X, Y, 'Learners', t, 'ObservationsIn', 'columns');
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

- “Quick Start Parallel Computing for Statistics and Machine Learning Toolbox” on page 27-2

Definitions

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the `LossFun` name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the true class and maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

kfoldMargin

Class: ClassificationPartitionedModel

Classification margins for observations not used for training

Syntax

```
M = kfoldMargin(obj)
```

Description

`M = kfoldMargin(obj)` returns classification margins obtained by cross-validated classification model `obj`. For every fold, this method computes classification margins for in-fold observations using a model trained on out-of-fold observations.

Input Arguments

obj

A partitioned classification model of type `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

Output Arguments

M

The classification margin.

Examples

Estimate the *k*-fold Margins of a Classifier

Find the *k*-fold margins for an ensemble that classifies the `ionosphere` data.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a classification ensemble of decision trees.

```
Mdl = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
```

Cross validate the classifier using 10-fold cross validation.

```
cvens = crossval(Mdl);
```

Compute the `_k_fold` margins. Display summary statistics for the margins.

```
m = kfoldMargin(cvens);
marginStats = table(min(m),mean(m),max(m),...
    'VariableNames',{'Min','Mean','Max'})
```

```
marginStats =
```

```
1×3 table
```

Min	Mean	Max
-11.312	7.3236	23.517

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix `X`. A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 17-7.

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as `true` when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

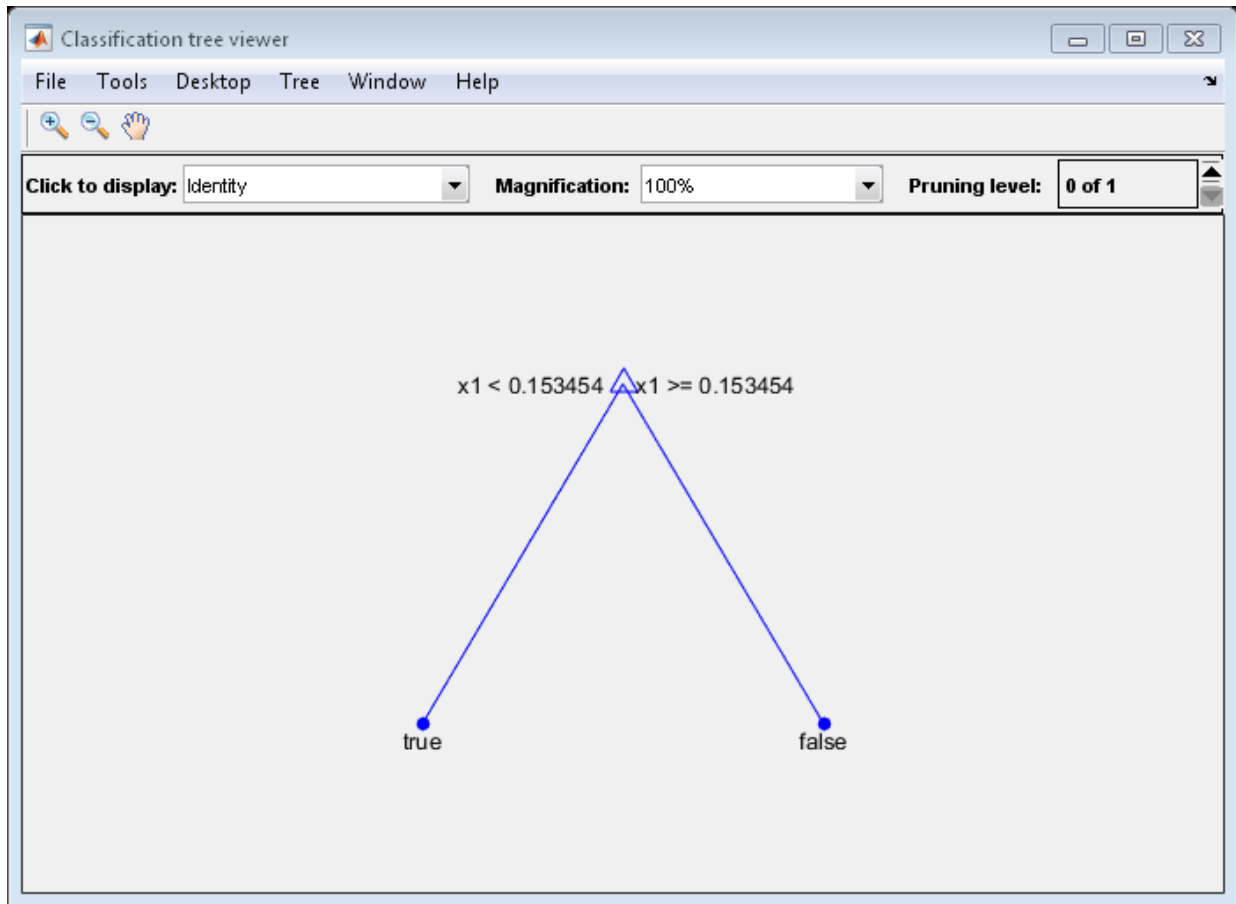

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =
  0.9059    0.0941    0.8147
  0.9059    0.0941    0.9058
         0     1.0000    0.1270
  0.9059    0.0941    0.9134
  0.9059    0.0941    0.6324
         0     1.0000    0.0975
  0.9059    0.0941    0.2785
  0.9059    0.0941    0.5469
  0.9059    0.0941    0.9575
  0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Topics

kfoldPredict

Class: ClassificationPartitionedECOC

Predict responses for observations not used for training

Syntax

```
label = kfoldPredict(CVMdl)
label = kfoldPredict(CVMdl,Name,Value)
[label,NegLoss,PBScore] = kfoldPredict(____)
[label,NegLoss,PBScore,Posterior] = kfoldPredict(____)
```

Description

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated ECOC model (ClassificationPartitionedECOC) `CVMdl`. That is, for every fold, `kfoldPredict` predicts class labels for observations that it holds out when it trains. `CVMdl.X` contains both sets of observations.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = kfoldPredict(CVMdl,Name,Value)` returns predicted class labels with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = kfoldPredict(____)` additionally returns negated values of the average binary loss per class (`NegLoss`) for in-fold observations, and positive-class scores (`PBScore`) for in-fold observations classified by each binary learner.

If the coding matrix varies across folds (that is, if the coding scheme is `sparsrandom` or `denserandom`), then `PBScore` is empty (`[]`).

`[label,NegLoss,PBScore,Posterior] = kfoldPredict(____)` additionally returns posterior class probability estimates for in-fold observations (`Posterior`).

To obtain posterior class probabilities, you must set `'FitPosterior', 1` when training the ECOC model using `fitcecoc`. Otherwise, `kfoldPredict` throws an error.

Input Arguments

CVMd1 — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model by:

- Passing a trained ECOC model (`ClassificationECOC`) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'`
| `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
<code>'binodeviance'</code>	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$

Value	Description	Score Domain	$g(y_i, s_i)$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_i s_i)/2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_i s_i)]/2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_i s_i)/2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_i s_i)/2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_i s_i)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_i(2s_i - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` should have this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 29-4911.

By default, if all binary learners are:

- SVMs or linear classification models of SVM learners, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`

- Linear classification models of logistic regression learners, or you specify to predict class posterior probabilities (i.e., set `'FitPosterior',1` in `fitcecoc`), then `BinaryLoss` is `'quadratic'`

Otherwise, the default `BinaryLoss` is `'hamming'`. To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `function_handle`

'Decoding' — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses on page 29-4919, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: `char`

'NumKLInitializations' — Number of random initial values

0 (default) | nonnegative integer

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of `'NumKLInitializations'` and a nonnegative integer.

If you do not request the fourth output argument (`Posterior`) and set `'PosteriorMethod','kl'` (the default), then the software ignores the value of `NumKLInitializations`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 29-4921.

Example: `'NumKLInitializations',5`

Data Types: `single` | `double`

'Options' — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

'PosteriorMethod' — Posterior probability estimation method

`'kl'` (default) | `'qp'`

Posterior probability estimation method, specified as the comma-separated pair consisting of `'PosteriorMethod'` and `'kl'` or `'qp'`.

- If `PosteriorMethod` is `'kl'`, then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 29-4921.
- If `PosteriorMethod` is `'qp'`, then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 29-4922.
- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: `'PosteriorMethod','qp'`

Data Types: char

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: single | double

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

label:

- Is the same data type as `CVMD1.Y`
- Has length equal to the number of rows of `CVMD1.X`

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

NegLoss — Negated average binary losses

numeric matrix

Negated average binary losses, returned as a numeric matrix. `NegLoss` is an n -by- K matrix, where n is the number of observations (`size(CVMD1.X,1)`) and K is the number of unique classes (`size(CVMD1.ClassNames,1)`).

PBScore — Positive-class scores

numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an n -by- L matrix, where n is the number of observations (`size(CVMD1.X,1)`) and L is the number of binary learners (`size(CVMD1.CodingMatrix,2)`).

If the coding matrix varies across folds (that is, if the coding scheme is `sparsrandom` or `denserandom`), then `PBScore` is empty (`[]`).

Posterior — Posterior class probabilities

numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an n -by- K matrix, where n is the number of observations (`size(CVMD1.X,1)`) and K is the number of unique classes (`size(CVMD1.ClassNames,1)`).

You must set `'FitPosterior', 1` when training the ECOC model using `fitcecoc` to request `Posterior`. Otherwise, the software throws an error.

Examples

Predict *k*-Fold Cross-Validation Labels of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize', 1);
CVMdl = fitcecoc(X, Y, 'CrossVal', 'on', 'Learners', t, 'ClassNames', classOrder);
```

`CVMdl` is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Predict the out-of-fold labels. Print a random subset of true and predicted labels.

```
labels = kfoldPredict(CVMdl);
idx = randsample(numel(labels), 10);
table(Y(idx), labels(idx), ...
      'VariableNames', {'TrueLabels', 'PredictedLabels'})
```

```
ans =
```

```
10×2 table
```

```
   TrueLabels   PredictedLabels
```

```
-----
```

```

setosa      setosa
versicolor versicolor
setosa      setosa
virginica   virginica
versicolor versicolor
setosa      setosa
virginica   virginica
virginica   virginica
setosa      setosa
setosa      setosa

```

CVMd1 correctly labeled the out-of-fold observations with indices `idx`.

Predict Cross-Validation Labels of ECOC Models Using Custom Binary Loss Function

Load Fisher's iris data set.

```

load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
K = numel(classOrder); % Number of classes
rng(1); % For reproducibility

```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```

t = templateSVM('Standardize',1);
CVMd1 = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);

```

CVMd1 is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

SVM scores are signed distances from the observation to the decision boundary.

Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that:

- Maps the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation
- Uses linear loss

- Aggregates the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 out-of-fold observations.

```
[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);
```

```
idx = randsample(numel(label),10);
classOrder
table(Y(idx),label(idx),NegLoss(idx,:), 'VariableNames',...
      {'TrueLabel', 'PredictedLabel', 'NegLoss'})
```

```
classOrder =
```

```
3×1 categorical array
```

```
setosa
versicolor
virginica
```

```
ans =
```

```
10×3 table
```

TrueLabel	PredictedLabel	NegLoss		
setosa	versicolor	0.37141	2.1292	-4.0006
versicolor	versicolor	-1.2169	0.36685	-0.64995
setosa	versicolor	0.23914	2.0795	-3.8187
virginica	virginica	-1.915	-0.19952	0.61451
versicolor	versicolor	-1.3744	0.45537	-0.58093
setosa	versicolor	0.20073	2.2777	-3.9784
virginica	versicolor	-1.4926	0.09073	-0.098159
virginica	virginica	-1.7667	-0.13462	0.40134
setosa	versicolor	0.20006	1.9112	-3.6112
setosa	versicolor	0.16108	1.9684	-3.6294

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results seem to indicate that the median of the linear losses might not perform as well as other losses.

Estimate Cross-Validation Posterior Probabilities of ECOC Models

Load Fisher's iris data set. Train the classifier using the petal dimensions as predictors.

```
load fisheriris
X = meas(:,3:4);
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Create an SVM template, and specify the Gaussian kernel. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.
